April 12, 2002

Abstract

Recently, the Description Logic (DL) $SHIQ$ has found a large number of applications. This success is due to the fact that $SHIQ$ combines a rich expressivity with efficient reasoning, as is demonstrated by its implementation in DL systems such as FaCT and RACER. One weakness of $SHIQ$, however, limits its usability in several application areas: numerical knowledge such as knowledge about the age, weight, or temperature of real-world entities cannot be adequately represented. In this paper, we propose an extension of $SHIQ$ that aims at closing this gap. The new Description Logic $\mathcal{Q}$-$SHIQ$, which augments $SHIQ$ by additional, “concrete domain” style concept constructors, allows to refer to rational numbers in concept descriptions, and also to define concepts based on the comparison of numbers via predicates such as $<$ or $\leq$. We argue that this kind of expressivity is needed in many application areas such as reasoning about the semantic web. We prove reasoning with $\mathcal{Q}$-$SHIQ$ to be $\text{ExpTime}$-complete (thus not harder than reasoning with $SHIQ$) by devising an automata-based decision procedure.

1 Motivation

Description Logics (DLs) are a family of knowledge representation formalisms, which are—apart from their classical application in KR—nowadays used in various application areas such as reasoning about entity relationship (ER) diagrams and providing a formal basis for the so-called semantic web [4; 5]. One of the most influential DLs proposed in the last years is the $SHIQ$ Description Logic, whose success is based on the following two facts: first, $SHIQ$ is a very expressive DL providing for, e.g., transitive roles, inverse roles, and number restrictions, but its reasoning problems are nevertheless decidable in $\text{ExpTime}$ [12]. Second, $SHIQ$ has been implemented in efficient DL systems such as FaCT and RACER, which can, despite the high worst-case complexity of reasoning with $SHIQ$, deal surprisingly well even with huge knowledge bases [9; 6]. Although, as we just argued, $SHIQ$'s expressive power is one of the main reasons for its success, there is still room for improvement. In particular, $SHIQ$ cannot adequately represent numerical knowledge such as knowledge about the age, weight, or temperature of real-world entities, which, as we will later discuss in more detail, is
crucial for many important applications [2; 11; 5; 15]. In this paper, we extend $SHIQ$ with a set of concept constructors that belong to the so-called concrete domain family of constructors and allow a straightforward representation of numerical knowledge. Let us view a concrete example of knowledge representation with the resulting DL, which is called $Q-SHIQ$. The concept

\[ \text{Grandfather} \sqcap \exists \text{age} \geq 91 \sqcap (\geq 20 \text{ relatives Human}) \sqcap \forall \text{relatives age}, \text{age} < \]

describes a Grandfather who is 91 years old, has at least 20 relatives (such constraints are called “number restrictions”), and is older than all of these relatives. Note that we can refer to rational numbers such as “91” and also compare numbers using predicates such as “$<$”. We should like to stress that $Q-SHIQ$ cannot only be used for toy examples like the one above, but rather is a contribution to several “serious” application areas. Let us briefly review three examples:

(1) As described in [3; 4], reasoning about ER diagrams is an important application area of Description Logics. More specifically, current proposals found in the literature use fragments of $SHIQ$ to encode ER diagrams. One shortcoming of this approach can be described as follows: ER diagrams make use of so-called attributes to represent non-relational data such as numbers and strings to be stored in the database. If $SHIQ$ is used for representing ER diagrams, constraints concerning the values of attributes cannot be expressed. To give a simple example, if there exists a relation Employee having two attributes Birthday and Employment-date, then it cannot be expressed that members of this relation should be born before they are employed. If $Q-SHIQ$ is used for representing ER diagrams, such numerical data constraints on attributes can easily be handled. This topic is discussed in more detail in [17].

(2) In [15; 14], the Description Logic $TDL$ is motivated as a valuable tool for the representation of temporal conceptual knowledge. $TDL$ can be obtained from the well-known DL $ALC$ [18] by adding general TBoxes and concrete domain style concept constructors that allow to represent relations between rational numbers such as “$=$” and “$<$”. Indeed, it is not hard to see that $TDL$ is a fragment of $Q-SHIQ$, but lacks much of its expressive power such as number restrictions and inverse roles. Thus, $Q-SHIQ$ is also well-suited for reasoning about temporal conceptual knowledge as described in [15; 14]. Moreover, $Q-SHIQ$ significantly extends the expressive power provided by $TDL$, even in the temporal/numerical component of the logic. For example, in $Q-SHIQ$ one can refer to concrete time points and intervals such as 4 or [1, 12] which is not possible in $TDL$.

(3) A rapidly developing application area of DLs is their use as an ontology language for the semantic web [5]. As noted in [5; 8], the representation of “concrete datatypes” such as numbers is an important task in this context. However, in DLs such as $OIL$ and $DAML+OIL$, which have been proposed in this application area, appropriate expressivity is either not provided or not taken into account for reasoning, which is done by a translation into $SHIQ$ or related DLs. In [11], Horrocks and Sattler propose to extend $SHIQ$, a close relative of $SHIQ$, with so-called unary concrete domains in order to integrate concrete datatypes. However, this solution is not really satisfying since, as is explained in more detail in [14], unary concrete domains are of
very limited expressivity. If $\mathcal{Q}$-$\mathcal{SHIQ}$ is used as the target logic in translations of OIL and DAML+OIL, a rather powerful means for describing numerical concrete datatypes becomes available.

As the main result of this paper, we prove reasoning with $\mathcal{Q}$-$\mathcal{SHIQ}$ to be decidable in ExpTime by devising an automata-based decision procedure. Thus, $\mathcal{Q}$-$\mathcal{SHIQ}$ sensibly enhances the expressive power of $\mathcal{SHIQ}$ without increasing the worst-case complexity of reasoning.

2 Syntax and Semantics

In this section, we introduce the Description Logic $\mathcal{Q}$-$\mathcal{SHIQ}$ in detail. We first give the syntax and semantics of $\mathcal{Q}$-$\mathcal{SHIQ}$-roles, then introduce some useful abbreviations, and finally define syntax and semantics of $\mathcal{Q}$-$\mathcal{SHIQ}$-concepts.

**Definition 2.1 ($\mathcal{Q}$-$\mathcal{SHIQ}$-roles).** Let $N_{\text{IR}}$, $N_{\text{IR}}$, and $N_{\text{AF}}$ be countably infinite and mutually disjoint sets of regular role names, transitive role names, and abstract features, respectively. Moreover, let $N_{\text{R}} = N_{\text{IR}} \uplus N_{\text{IR}} \uplus N_{\text{AF}}$. The set of $\mathcal{Q}$-$\mathcal{SHIQ}$-roles $\mathcal{ROL}$ is $N_{\text{R}} \cup \{ R^{-} \mid R \in N_{\text{R}} \}$. A role inclusion is of the form

$$R \sqsubseteq S,$$

for $R, S \in \mathcal{ROL}$. A role hierarchy is a set of role inclusions.

An interpretation $\mathcal{I} = (\Delta^{\mathcal{I}}, \cdot^{\mathcal{I}})$ consists of a set $\Delta^{\mathcal{I}}$, called the domain of $\mathcal{I}$, and a function $\cdot^{\mathcal{I}}$ which maps every role $R \in \mathcal{ROL}$ to a subset $R^{\mathcal{I}}$ of $\Delta^{\mathcal{I}} \times \Delta^{\mathcal{I}}$ such that, for $R \in N_{\text{R}}, S \in N_{\text{IR}}$, and $f \in N_{\text{AF}},$

$$(x, y) \in R^{\mathcal{I}} \text{ iff } (y, x) \in R^{-^{\mathcal{I}}},$$

if $(x, y) \in S^{\mathcal{I}}$ and $(y, z) \in S^{\mathcal{I}}$, then $(x, z) \in S^{\mathcal{I}}$, and $f^{\mathcal{I}}$ is functional.

An interpretation $\mathcal{I}$ is a model of a role hierarchy $\mathcal{R}$ iff $R^{\mathcal{I}} \subseteq S^{\mathcal{I}}$ for each $R \sqsubseteq S \in \mathcal{R}$. $\diamond$

We introduce some notation to make the following considerations easier.

1. The function $\text{Inv}$ yields the inverse of a role. More precisely, for $R \in \mathcal{ROL}$, we set

$$\text{Inv}(R) := \begin{cases} R^{-} & \text{if } R \text{ is a role name}, \\ S & \text{if } R = S^{-} \text{ for a role name } S. \end{cases}$$

2. Since set inclusion is transitive and $R^{\mathcal{I}} \subseteq S^{\mathcal{I}}$ implies $\text{Inv}(R)^{\mathcal{I}} \subseteq \text{Inv}(S)^{\mathcal{I}}$, for a role hierarchy $\mathcal{R}$, we introduce $\sqsubseteq^{\mathcal{R}}$ as the reflexive-transitive closure of

$$\mathcal{R} \cup \{ \text{Inv}(R) \sqsubseteq \text{Inv}(S) \mid R \sqsubseteq S \in \mathcal{R} \}.$$
3. We call a role $R \in \text{ROL}$ \textit{transitive} with respect to a role hierarchy $\mathcal{R}$ iff $R$ is interpreted in a transitive relation in every model of $\mathcal{R}$. It is not hard to see that this is the case iff the following predicate evaluates to true:

$$\text{Trans}_{\mathcal{R}}(R) := \begin{cases} 
\text{true} & \text{if there exists a role } S \in \mathbb{N}_R \text{ such that } S' \sqsubseteq_\mathcal{R} R \text{ and } \quad R \sqsubseteq_\mathcal{R} S'' \text{ for some } S', S'' \in \{\text{inv}(S)\} \\
\text{false} & \text{otherwise}
\end{cases}$$

4. A role $R \in \text{ROL}$ is called \textit{simple} with respect to a role hierarchy $\mathcal{R}$ iff $\text{Trans}_{\mathcal{R}}(S)$ does not hold for any $S \in \text{ROL}$ with $S \subseteq R$.

For both "$\sqsubseteq_\mathcal{R}$" and $\text{Trans}_{\mathcal{R}}$, we omit the index if clear from the context. Note that no transitive role is simple since $\sqsubseteq$ is defined as the \textit{reflexive}-transitive closure. For the same reason, we have $\text{Trans}(R)$ for all $R \in \mathbb{N}_R$. However, roles must obviously not be in $\mathbb{N}_R$ in order to be transitive. For example, if $R \in \mathbb{N}_R$, then $R^-$ is also transitive. Similarly, if $S \in \mathbb{N}_R$, $R \not\in \mathbb{N}_R$, $S^- \sqsubseteq R$, $R \sqsubseteq S^-$, then $R$ is transitive. We are now ready to define $\mathcal{Q}$-$\mathcal{S\mathcal{H}\mathcal{I}\mathcal{Q}}$-concepts and their semantics.

**Definition 2.2 ($\mathcal{Q}$-$\mathcal{S\mathcal{H}\mathcal{I}\mathcal{Q}}$-concepts).** Let $\mathbb{N}_c$ and $\mathbb{N}_{cf}$ be countably infinite sets of \textit{concept names} and \textit{concrete features}, respectively, such that $\mathbb{N}_c$, $\mathbb{N}_r$, and $\mathbb{N}_{cf}$ are mutually disjoint. A \textit{path} is a sequence $R_1 \cdots R_k g$ consisting of roles $R_1, \ldots, R_k \in \text{ROL}$ and a concrete feature $g \in \mathbb{N}_{cf}$. A path $R_1 \cdots R_k g$ with $\{R_1, \ldots, R_k\} \subseteq \mathbb{N}_{cf}$ is called \textit{feature path}. The set of $\mathcal{Q}$-$\mathcal{S\mathcal{H}\mathcal{I}\mathcal{Q}}$-\textit{concepts} is the smallest set such that

1. every concept name $C \in \mathbb{N}_c$ is a concept,
2. if $C$ and $D$ are concepts and $R \in \text{ROL}$, then $C \sqcap D, C \sqcup D, \neg C, \forall R.C$, and $\exists R.C$ are concepts,
3. if $C$ is a concept, $R \in \text{ROL}$ is simple, and $n \in \mathbb{N}$, then $(\leq n R C)$ and $(\geq n R C)$ are concepts,
4. if $u_1$ and $u_2$ are feature paths and $P \in \{<, \leq, =, \neq, \geq, >\}$, then $\exists u_1, u_2 P$ and $\forall u_1, u_2 P$ are concepts,
5. if $R \in \text{ROL}$ is simple, $g_1$ and $g_2$ are concrete features, and $P \in \{<, \leq, =, \neq, \geq, >\}$, then $\exists R g_1, g_2 P$ and $\forall R g_1, g_2 P$ are concepts, and
6. if $g$ is a concrete feature, $P \in \{<, \leq, =, \neq, \geq, >\}$, and $q \in \mathbb{Q}$, then $\exists g P_q$ is a concept.

We use $\top$ as an abbreviation for $A \sqcup \neg A$ (for some fixed $A \in \mathbb{N}_c$). The interpretation function $^\mathcal{I}$ of interpretations $\mathcal{I} = (\Delta^\mathcal{I}, ^\mathcal{I})$ maps, additionally,

- every concept $C$ to a subset $C^\mathcal{I}$ of $\Delta^\mathcal{I}$ and
- every concrete feature $g$ to a partial function $g^\mathcal{I}$ from $\Delta^\mathcal{I}$ to the set of rational numbers $\mathbb{Q}$.
such that

\[(C \cap D)^I = C^I \cap D^I,\]
\[(C \cup D)^I = C^I \cup D^I,\]
\[-C^I = \Delta^I \setminus C^I,\]
\[(\exists R. C)^I = \{x \in \Delta^I \mid \text{there is some } y \in \Delta^I \text{ with } (x, y) \in R^I \text{ and } y \in C^I\},\]
\[(\forall R. C)^I = \{x \in \Delta^I \mid \text{for all } y \in \Delta^I, \text{ if } (x, y) \in R^I \text{ then } y \in C^I\},\]
\[(\leq n R C)^I = \{x \in \Delta^I \mid \#\{y \mid (x, y) \in R^I \text{ and } y \in C^I\} \leq n\},\]
\[(\geq n R C)^I = \{x \in \Delta^I \mid \#\{y \mid (x, y) \in R^I \text{ and } y \in C^I\} \geq n\},\]
\[(\exists U_1, U_2, P)^I = \{x \in \Delta^I \mid \text{there are } q_1 \in U_1^I \text{ and } q_2 \in U_2^I \text{ with } q_1 P q_2\}\]
\[(\forall U_1, U_2, P)^I = \{x \in \Delta^I \mid \text{for all } q_1 \in U_1^I \text{ and } q_2 \in U_2^I, \text{ we have } q_1 P q_2\}\]
\[(3g. Pq)^I = \{x \in \Delta^I \mid g^I(x) P q\}\]

where $U_1$ and $U_2$ denote paths, \#S denotes the cardinality of the set $S$, and, for every path $U = R_1 \cdots R_k g$, $U^I$ is defined as

\[(x, q) \subseteq \Delta^I \times \mathbb{Q} \mid \exists y_1, \ldots, y_{k+1} : x = y_1, (y_i, y_{i+1}) \in R_i^I \text{ for } 1 \leq i \leq k, \text{ and } g^I(y_{k+1}) = q.\]

An interpretation $I$ is called a model of a concept $C$ iff $C^I \neq \emptyset$. $C$ is called satisfiable with respect to a role hierarchy $\mathcal{R}$ iff there exists a model of $C$ and $\mathcal{R}$. A concept $D$ subsumes a concept $C$ with respect to $\mathcal{R}$ (written $C \sqsubseteq_R D$) iff $C^I \subseteq D^I$ holds for each model $I$ of $\mathcal{R}$. Two concepts $C, D$ are equivalent with respect to $\mathcal{R}$ (written $C \equiv_R D$) iff they are mutually subsuming.

In the following sections, we show that $\mathcal{Q}$-SHIQ-concept satisfiability is decidable in deterministic exponential time. This also yields decidability and an ExpTime upper complexity bound for concept subsumption and equivalence: we have (i) $C \sqsubseteq_R D$ iff $C \cap \neg D$ is unsatisfiable w.r.t. $\mathcal{R}$ and (ii) $C \equiv_R D$ iff $C \sqsubseteq_R D$ and $D \sqsubseteq_R C$.

Throughout this paper, we denote concept names by $A$ and $B$, concepts by $C$, $D$, and $E$, roles by $P$, $R$, and $S$, abstract features by $f$, concrete features by $g$, paths by $U$, feature paths by $u$, and predicates by $P$.

Let us discuss the $\mathcal{Q}$-SHIQ-concept language in some more detail. Since exhaustive information on SHIQ can be found in, e.g., [12], we concentrate on the additional concept constructors $\exists U_1, U_2, P, \forall U_1, U_2, P, \text{ and } \exists g. Pq$, which, as has already been noted, are often called “concrete domain constructors”. Concrete domains have been introduced by Baader and Hanschke [1] as a means for representing “concrete knowledge” such as knowledge about numbers, strings, or spatial extensions. More precisely, Baader and Hanschke extend the basic propositionally closed DL $\mathcal{ALC}$ with concrete domains, where a concrete domain $\mathcal{D}$ is comprised of a set called the domain and a set of predicates with a fixed extension on this domain. However, Baader and Hanschke do not commit themselves to a particular concrete domain, but rather view the concrete domain as a parameter to their logic, which they call $\mathcal{ALC}(\mathcal{D})$. From the concrete domain perspective, $\mathcal{Q}$-SHIQ can be viewed as being equipped with one particular concrete domain, whose domain are the rationals and which is equipped
with binary predicates $<, \leq, =, \neq, \geq, >$ and unary predicates $P_q$, where $q \in Q$ and $P \in \{<, \leq, =, \neq, \geq, >\}$.

The paths $U_1$ and $U_2$ that may appear inside $Q$-SHIQ's binary concrete domain constructors $\exists U_1, U_2 \cdot P$ and $\forall U_1, U_2 \cdot P$ are of a rather special form: either (i) $U_1$ and $U_2$ are feature paths or (ii) $U_1$ has the form $Rg_1$ and $U_2$ has the form $g_2$. Let us illustrate the expressive power of these two variants of the same constructors: using Variant (i), we can, e.g., describe people whose mother’s spouse earns more than their father (we use parentheses for better readability):

$$\exists (\text{mother spouse wage}), (\text{father wage}). >$$

This example illustrates the main advantage of Variant (i): we can talk about sequences of features. This variant of $Q$-SHIQ’s binary concrete domain constructors are precisely the concrete domain constructors offered by $\mathcal{ALC}(\mathcal{D})$ and the temporal DL $\mathcal{TDL}$ mentioned in the introduction. The main disadvantage of Variant (i) is that, inside paths, we may only use abstract features but no roles from $N_{IR}$. For example, if we want to describe people having an older neighbor by the concept

$$\exists (\text{neighbor}, \text{age}), (\text{age}). >,$$

then “neighbor” should clearly be from $N_{IR}$ rather than from $N_{AF}$, since otherwise we would enforce that the described persons have at most a single neighbor. Therefore, we need Variant (ii) of the binary concrete domain constructors to define this concept. Note that Variant (ii) is neither provided by $\mathcal{ALC}(\mathcal{D})$ nor by $\mathcal{TDL}$, but rather is a restricted version of the concrete domain constructors defined in [7].

It is not hard to see that we could also have admitted variants $\exists g_1, Rg_2 \cdot P$ and $\forall g_1, Rg_2 \cdot P$ of the binary concrete domain constructors since this variant is just syntactic sugar: $\exists g_1, Rg_2 \cdot P$ is equivalent to $\exists Rg_2, g_1 \cdot P$ and $\forall g_1, Rg_2 \cdot P$ is equivalent to $\forall Rg_2, g_1 \cdot P$, where $\overline{P}$ denotes the inverse of the predicate $P$—for example, “$<$” is “$>$” and “$=$” is “$=\sim$”. Obviously, the most general approach would be to allow arbitrary paths inside the binary concrete domain constructors. The resulting logic, however, cannot easily be handled by the ExpTime decision procedure for concept satisfiability presented in the remainder of this paper. Indeed, it is currently not even clear whether the resulting logic is decidable.

It may look strange at first sight that $Q$-SHIQ provides for both abstract features and number restrictions since, as is well-known, number restrictions, transitive roles, and role hierarchies can be used to enforce that a role $R_f$ from $N_{IR}$ is interpreted functionally; just use the concept $\forall R \cdot (1 \ldots R_f \cdot \top)$, where $R \in N_{IR}$, and employ the role hierarchy to ensure that $S \subseteq R$ for every “relevant” role $S$ (e.g. for the roles occurring in the concept or role hierarchy whose satisfiability is to be decided). The reason for this redundancy is that number restrictions are, in principle, a more general means of expressivity than abstract features, but having abstract features explicitly available allows for a straightforward definition of Variant (i) of the concrete domain constructors.

---

1 Admitting arbitrary paths inside the unary concrete domain constructor is not an issue since the concept $\exists R_1 \ldots R_k g \cdot P_q$ (with the obvious semantics) can be written as $\exists R_1, \ldots, \exists R_k, \exists g \cdot P_q$. 
Note that only simple roles are allowed in Variant (ii) of the binary concrete domain constructor. Similarly, roles used inside number restrictions are also required to be simple. As proved in [12], the latter restriction is crucial since admitting non-simple roles inside number restrictions yields undecidable reasoning problems. Non-simple roles inside the binary concrete domain constructors cannot be handled by the \textsc{ExpTime} decision procedure in its current form. Again, it is as of now unknown whether admitting them yields undecidability of reasoning.

There exist existential and universal versions of the binary concrete domain constructors but only an existential version of the unary concrete domain constructor. It is not hard to see that we could also have admitted a universal version since $\forall g.P_q$ (with the obvious semantics) is clearly equivalent to $\forall g, g \neq \exists g.P_q$, where $\forall g, g \neq \exists g$ simply expresses that there exists no successor for the concrete feature $g$. Similarly, the universal version of Variant (i) of the binary concrete domain constructors can be expressed in terms of the existential version of Variant (i) of this constructor. This does, however, not hold for Variant (ii) of the binary concrete domain constructors since it accepts non-functional roles as arguments. For this reason, we have chosen to include universal versions of both Variant (i) and (ii) for uniformity.

Most modern Description Logics do not only consist of a concept language but also provide for a TBox component. Formally, a TBox is a finite set of concept equations $C = D$, where $C$ and $D$ are $\mathcal{Q}$-\textsc{SHIQ}-concepts. An interpretation $I$ is a model of a TBox $\mathcal{T}$ iff it satisfies $C^I = D^I$ for all $(C = D) \in \mathcal{T}$. In the presence of TBoxes, one is usually interested in the satisfiability of concepts w.r.t. TBoxes and role hierarchies, where a concept $C$ is satisfiable w.r.t. a TBox $\mathcal{T}$ and a role hierarchy $\mathcal{R}$ iff there exists a model $I$ of $C$, $\mathcal{T}$, and $\mathcal{R}$. However, as was shown in [10], in the presence of role hierarchies and transitive roles it is possible to polynomially reduce concept satisfiability w.r.t. TBoxes and role hierarchies to concept satisfiability w.r.t. role hierarchies, only. This is done using a rather straightforward technique known as “internalization”. Because of this, we will not explicitly consider TBoxes in this paper. They can, however, easily be treated by internalization.

3 Preliminaries

Decidability and the \textsc{ExpTime} upper complexity bound for $\mathcal{Q}$-\textsc{SHIQ}-concept satisfiability is established by devising an automata-based decision procedure. The general idea behind this procedure is to define, for a given concept $C$ and role hierarchy $\mathcal{R}$, a looping tree-automaton $A_{C, \mathcal{R}}$ that accepts exactly the so-called Hintikka-trees for $C$ and $\mathcal{R}$. These Hintikka-trees are abstractions of models of $C$ and $\mathcal{R}$, i.e., $C$ and $\mathcal{R}$ have a model if and only if $C$ and $\mathcal{R}$ have a Hintikka-tree. The obvious advantage of Hintikka-trees over models is that they are trees and thus amenable to tree automata techniques. Once the automaton $A_{C, \mathcal{R}}$ is defined, it remains to apply the standard emptiness test for tree automata: clearly, the language accepted by the constructed automaton is empty iff $C$ is satisfiable w.r.t. $\mathcal{R}$.

In this section, we introduce the basic notions underlying the decision procedure sketched above. We start with developing a useful normal form (called \textit{path normal}}
form) for $\mathcal{Q}$-$SHIQ$-concepts, and then introduce looping tree-automata, whose theory forms the basis for the decision algorithm. Finally, we define constraint graphs, which will play an important role in representing the “numerical part” of $\mathcal{Q}$-$SHIQ$-interpretations in Hintikka-trees.

### 3.1 Normal Forms

We start with formulating a property of role hierarchies that we will generally assume to be satisfied in what follows:

A role hierarchy $\mathcal{R}$ is called *admissible* iff all $f \in N_{sf}$ are simple w.r.t. $\mathcal{R}$.

Demanding admissibility of role hierarchies is closely related to requiring roles $R$ that appear inside number restrictions ($\leq n R C$) and ($\geq n R C$) to be simple: since abstract features are interpreted in functional relations, they are “inherently number restricted”, i.e., for each $f \in N_{sf}$, ($\leq 1 f \top$) is satisfied by every domain element in every interpretation. However, it seems that, in contrast to admitting arbitrary roles inside number restrictions, dropping admissibility of role hierarchies does not necessarily lead to undecidability of reasoning. Indeed, we claim that the decision procedure presented in this paper can, in principle, be extended to also deal with non-admissible role hierarchies. We nevertheless restrict ourselves to admissible role hierarchies since (i) this eliminates several case distinctions in the proofs, and (ii) we agree with Horrocks and Sattler [10] who argue that non-simple features are rather unnatural: if $f \in N_{sf}$ is non-simple, then there exists a role $R \in N_R$ such that $\text{Trans}(R)$ and $R \equiv f$. Hence, $R$ is both functional and transitive which produces strange effects: for any interpretation $\mathcal{I}$, $R^\mathcal{I}$ may not contain any acyclic paths of length greater 1.

Hence, the concept $\exists R \exists R \top$ is satisfiable only in models that contain either (i) a domain element $a$ which is its own $R$-successor or (ii) two domain elements $a$ and $b$, where $b$ is $R$-successor of $a$ and of itself (the same holds for the concept $\exists R : \exists R : \exists R \top$). To avoid such effects, which do not seem to promote writing understandable knowledge bases, we generally require role hierarchies to be admissible.

Let us now turn our attention towards normal forms for $\mathcal{Q}$-$SHIQ$-concepts. We first introduce the well-known negation normal form.

**Definition 3.1 (NNF).** A concept $C$ is in *negation normal form* (NNF) if negation occurs only in front of concept names. Exhaustive application of the following rewrite rules translates concepts to equivalent ones in NNF.

\[
\begin{align*}
\neg \neg C & \iff C \\
\neg (C \sqcap D) & \iff \neg C \sqcup \neg D \\
\neg (\forall R. C) & \iff (\exists R. \neg C) \\
\neg (\exists U_1, U_2. P) & \iff \forall U_1, U_2. \overline{P} \\
\neg (\exists g. P_\alpha) & \iff \forall g, g \neq \alpha \exists g. \overline{P}_\alpha
\end{align*}
\]

where $\overline{P}$ denotes the negation of predicates, e.g. “$\geq\neg$” is “$\geq$” and “$\neg\neg$” is “$=$”. By $\text{nnf}(C)$, we denote the result of converting $C$ into NNF using the above rules. Furthermore, we use $\neg C$ as a shorthand for $\text{nnf}(\neg C)$.

\[\Diamond\]
Note that, in the \( \neg(\exists y.P_y) \) case of the NNF rewrite rules, the concept \( \forall y, p \neq \) is only used to express that there exists no \( g \)-successor at all. We now introduce path normal form, which was first described in [15] in the context of the Description Logic \( \mathcal{TDL} \) mentioned in the introduction.

**Definition 3.2 (Path Normal Form).** A \( \mathbb{Q}-\mathcal{SHIQ} \)-concept \( C \) is in path normal form (PNF) if it is in NNF and, for all subconcepts \( \exists U_1, U_2. P \) and \( \forall U_1, U_2. P \) of \( C \), we have either

1. \( U_1 = g_1 \) and \( U_2 = g_2 \) for some \( g_1, g_2 \in \mathbb{N}_c \) or
2. \( U_1 = Rg_1 \) and \( U_2 = g_2 \) for some \( R \in \mathbb{N}_a \cup \mathbb{N}_r \) and \( g_1, g_2 \in \mathbb{N}_c \).

\( \diamond \)

The following lemma shows that we can w.l.o.g. assume \( \mathbb{Q}-\mathcal{SHIQ} \)-concepts to be in PNF.

**Lemma 3.3.** Satisfiability of \( \mathbb{Q}-\mathcal{SHIQ} \)-concepts can be polynomially reduced to satisfiability of \( \mathbb{Q}-\mathcal{SHIQ} \)-concepts in PNF.

**Proof** We first define an auxiliary mapping and then use this mapping to translate \( \mathbb{Q}-\mathcal{SHIQ} \)-concepts into equivalent ones in PNF. Let \( C \) be a \( \mathbb{Q}-\mathcal{SHIQ} \)-concept. For every feature path \( u = f_1 \cdots f_n g \) used in \( C \), we assume that \( [g], [f_n g], \ldots, [f_1 \cdots f_n g] \) are concrete features not used in \( C \). We inductively define a mapping \( \lambda \) from concrete paths \( u \) in \( C \) to concepts as follows:

\[
\begin{align*}
\lambda(g) &= \top \\
\lambda(fu) &= (\exists [fu], f[u], =) \cap \exists f. \lambda(u)
\end{align*}
\]

For every \( \mathbb{Q}-\mathcal{SHIQ} \)-concept \( C \), a corresponding concept \( \rho(C) \) is obtained by

- first replacing all subconcepts \( \forall u_1, u_2. P \) where \( u_i = \underbrace{f_1^{(i)} \cdots f_{k_i}^{(i)} g_i}_{i \in \{1, 2\}} \) with

\[
\forall f_1^{(1)} \cdots \forall f_{k_1}^{(1)} \forall g_1, g_1 \neq \sqcup \forall f_1^{(2)} \cdots \forall f_{k_2}^{(2)} \forall g_2, g_2 \neq \sqcup \exists u_1, u_2. P
\]

- and then replacing all subconcepts \( \exists u_1, u_2. P \) with \( \exists [u_1], [u_2]. P \cap \lambda(u_1) \cap \lambda(u_2) \).

Now let \( C \) be a \( \mathbb{Q}-\mathcal{SHIQ} \)-concept. Using the rewriting rules from Definition 3.1, we can convert \( C \) into an equivalent concept \( C' \) in NNF. It is then easy to check that \( C' \) is satisfiable iff \( \rho(C') \) is satisfiable. Moreover, \( \rho(C') \) is clearly in PNF and the translation can be done in polynomial time. \( \square \)
Intuitively, Lemma 3.3 states that Variant (i) of the binary concrete domain constructors discussed in the previous section can be reduced to the forms $\exists f_{g_1}, g_2. P$ and $\exists g_1, g_2. P$. Variant (ii) of the binary concrete domain constructors does not need to be manipulated in order to fit into the PNF scheme. Let us remark that our algorithm’s need for PNF is the reason why we cannot handle arbitrary paths inside the binary concrete domain constructors: it is an interesting exercise to check that the constructor $\forall U_1, U_2. P$ with $U_1 = R_1 \ldots R_n g$ and $U_2 = S_1 \ldots S_m g'. P$ can be reduced to the forms $\exists R g_1, g_2. P$ and $\exists g_1, g_2. P$ if $P \in \{<, \leq, =, \geq, >\}$ but not if $P$ is “$\neq$”.

### 3.2 Automata and Constraint Graphs

The automata used in this paper are so called looping tree-automata which can roughly be described as Büchi tree-automata where every run is accepting [21; 19]

**Definition 3.4 (Looping automaton).** Let $M$ be a set and $k \geq 1$. A $k$-ary $M$-tree is a mapping $T : \{1, \ldots, k\}^* \rightarrow M$ that labels each node $\alpha \in \{1, \ldots, k\}^*$ with $T(\alpha) \in M$. Intuitively, the node $\alpha_i$ is the $i$-th child of $\alpha$. We use $\epsilon$ to denote the empty word (corresponding to the root of the tree).

A looping automaton $A = (Q, M, I, \Delta)$ for $k$-ary $M$-trees is defined by a finite set $Q$ of states, a finite alphabet $M$, a subset $I \subseteq Q$ of initial states, and a transition relation $\Delta \subseteq Q \times M \times Q^k$.

A run of $A$ on an $M$-tree $T$ is a mapping $r : \{1, \ldots, k\}^* \rightarrow Q$ with $r(\epsilon) \in I$ and

$$r(\alpha), T(\alpha), r(\alpha_1), \ldots, r(\alpha_k) \in \Delta$$

for each $\alpha \in \{1, \ldots, k\}^*$. A looping automaton accepts all those $M$-trees for which there exists a run, i.e., the language $L(A)$ of $M$-trees accepted by $A$ is

$$L(A) := \{T \mid \text{there is a run of } A \text{ on } T\}.$$ 

Vardi and Wolper [21] show that the emptiness problem for looping automata, i.e., the problem to decide whether the language $L(A)$ accepted by a given looping automaton $A$ is empty, is decidable in polynomial time.

We now introduce constraint graphs. Such graphs are used to represent the “numerical part” of $Q$-$SHT\alpha$-interpretations in Hintikka-trees. A detailed description of how this is done, however, is delayed until Section 4, where Hintikka trees are defined.

**Definition 3.5 (Constraint graph).** A constraint graph is a directed graph $G = (V, E, \tau)$, where $V$ is a countable set of nodes,

$$E \subseteq V \times V \times \{<, \leq, =, \neq, \geq, >\}$$

is a set of labeled edges, and

$$\tau \subseteq V \times \{P_q \mid P \in \{<, \leq, =, \neq, \geq, >\} \text{ and } q \in Q\}$$

is a node labeling function. For simplicity, we generally assume that constraint graphs are equality closed, i.e., that we have $(v_1, v_2, =) \in E$ iff $(v_2, v_1, =) \in E$ for all $v_1, v_2 \in V$.
For a set of edges \( E \), we use \( \text{cl}_=(E) \) to denote the equality closure of \( E \) which is defined in the obvious way. In what follows, we sometimes write \( \tau(v) \) for \( \{ P_q \mid (v, P_q) \in \tau \} \).

A constraint graph \( G = (V, E, \tau) \) is called satisfiable over \( S \)—where \( S \) is a set equipped with a total ordering \(<\)—iff there exists a total mapping \( \phi \) from \( V \) to \( S \) such that

1. \((v) P q \) for all \( P_q \in \tau(v) \) and
2. \((v_1) P (v_2) \) for all \( (v_1, v_2, P) \in E \).

Such a mapping \( \phi \) is called a solution for \( G \). \( \Diamond \)

We will see later that every Hintikka-tree \( T \) induces a constraint graph which represents the “numerical part” of the canonical interpretation described by \( T \). As should be intuitively clear, these induced constraint graphs have to be satisfiable in order for Hintikka-trees to be proper abstractions of interpretations. Since, later on, we must define looping automata which accept exactly the Hintikka-trees for a concept \( C \) and role hierarchy \( R \), such automata should be able to verify the satisfiability of (induced) constraint graphs. This check is the main problem to be solved when developing an automata-based decision procedure for \( Q\-SHIQ \)-concept satisfiability: the induced constraint graph and its satisfiability are “global” notions while automata work “locally”. This problem can be overcome as follows: first, we define Hintikka trees such that their induced constraint graphs have a certain form (we will call such constraint graphs normal); second, we formulate an adequate criterion for the satisfiability of normal constraint graphs; and third, we show how this criterion can be verified by “local tests” that can be performed by automata. Let us start with introducing normal constraint graphs and the criterion for their satisfiability, which is called consistency.

**Definition 3.6 (Normal, \(<\)-cycle, Consistent).** Let \( G = (V, E, \tau) \) be a constraint graph. \( G \) is called normal if it satisfies the following conditions:

1. \((v_1, v_2, P) \in E \) implies \( P \in \{<,=\} \),
2. \((v, P_q) \in \tau \) implies \( P \in \{<,=,>\} \),
3. for each rational number \( q \) appearing in \( \tau \) and each node \( v \in V \), we have \((v, P_q) \in \tau \) for some \( P \in \{<,=,>\} \).

A path \( Q \) in a normal constraint graph \( G \) is a finite non-empty sequence of nodes \( v_0, \ldots, v_k \in V \) such that, for all \( i < k \), there exists a \( P \) such that \((v_i, v_{i+1}, P) \in E \). Such a path is also called a path from \( v_0 \) to \( v_k \). A path \( v_0, \ldots, v_k \) is a \( P \)-path for \( P \in \{<,=\} \) iff \((v_i, v_{i+1}, P) \in E \) for some \( i < k \). Moreover, \( v_0, \ldots, v_k \) is a strict \( P \)-path for \( P \in \{<,=\} \) iff \((v_i, v_{i+1}, P) \in E \) for each \( i < k \).

A cycle \( O \) in \( G \) is a path \( v_0, \ldots, v_k \) for which there exists a \( P \) such that \((v_k, v_0, P) \in E \). For \( i \leq k \), we use \( i_O \) to denote \((i + 1) \mod (k + 1)\), i.e., \( i_O \) denotes the index following \( i \) in the cycle \( O \). The index \( -O \) is omitted if clear from the context. A cycle \( O = v_0, \ldots, v_k \) is a \(<\)-cycle iff \((v_i, v_{i+1}, <) \in E \) for some \( i \) with \( i \leq k \).

A normal constraint graph \( G \) is consistent iff it satisfies the following conditions:
1. G contains no < -cycle,

2. for all v ∈ V, there exists a q ∈ Q such that qPq' for all P_q' ∈ τ(v),

3. for all (v_1, v_2, P) ∈ V, there exist q_1, q_2 ∈ Q such that

   - q_1 P q_2,
   - q_1 P' q for all P'_q ∈ τ(v_1), and
   - q_2 P' q for all P'_q ∈ τ(v_2).

It may appear that Property 3 of consistency is too weak since it only demands the existence of rationals q_1, q_2 for each edge between v_1 and v_2 separately instead of for all such edges simultaneously: a normal constraint graph with set of edges \{(v_1, v_2, <), (v_1, v_2, =)\} is clearly unsatisfiable, but does not violate Property 3. This, however, is compensated by Property 1 which is violated in this example.

We now show that consistency is indeed an adequate criterion for the satisfiability of normal constraint graphs.

**Theorem 3.7.** A normal constraint graph G is satisfiable over Q iff G is consistent.

**Proof** Since the “only if” direction is trivial, we concentrate on the “if” direction. Let G be a normal constraint graph that is consistent. We define a relation ∼ on V by setting v_1 ∼ v_2 iff v_1 = v_2 or there exists a strict = -path between v_1 and v_2. Since constraint graphs are assumed to be equality closed, ∼ is an equivalence relation. For v ∈ V, we denote the equivalence class of v w.r.t. ∼ by [v]. Define a new constraint graph G' = (V', E', τ') as follows:

\[
V' := \{[v] \mid v ∈ V\}
\]

\[
E' := \{(\{v_1\}, \{v_2\}, <) \mid \exists v'_1, v'_2 ∈ V \text{ such that } v'_1 ∈ [v_1], v'_2 ∈ [v_2], \text{ and } (v'_1, v'_2, <) ∈ E\}
\]

\[
τ' := \bigcup_{v' ∈ [v]} τ(v')
\]

It is not hard to check that G' is normal. Moreover, G' is consistent, i.e., it satisfies Properties 1 to 3 from Definition 3.6:

1. Assume that there is a < -cycle [v_0], ..., [v_k] in G'. Since G' contains no = -edges”, we have ([v_i], [v_{i+1}], <) ∈ E' for i ≤ k. By construction of G', there exist x_0, ..., x_k, y_0, ..., y_k ∈ V such that, for i ≤ k, we have x_i, y_i ∈ [v_i] and (x_i, y_{i+1}, <) ∈ E. Moreover, for i ≤ k, it holds that either y_i = x_i or there exists a strict = -path between y_i and x_i in G. This obviously implies that G contains a < -cycle which contradicts the assumption that G satisfies Property 1.

2. Let [v] ∈ V'. Since G satisfies Properties 2 and 3 of normality and Property 3 of consistency, the existence of a strict = -path from a node v_1 ∈ V to a node
\( v_2 \in V \) implies that \( \tau(v_1) = \tau(v_2) \). This, in turn, implies that \( \tau(v') = \tau'(\{v\}) \) for all \( v' \in \{v\} \). Thus, since \( G \) satisfies Property 2 of consistency, it is clear that \( G' \) also satisfies Property 2.

3. Let \( ([v_1],[v_2],P) \in E' \). By definition of \( G' \), this implies that \( P \) is \( <\)-acyclic. By definition of \( G' \) there exist \( v'_1 \in [v_1] \) and \( v'_2 \in [v_2] \) such that \( (v'_1,v'_2,\prec) \in E \). As in the previous case, we have \( \tau(v'_1) = \tau'(\{v_1\}) \) for all \( v' \in \{v_1\} \) and similar for \( v_2 \). Thus, \( \tau(v'_1) = \tau'(\{v_1\}) \) and \( \tau(v'_2) = \tau'(\{v_2\}) \). Since \( G \) satisfies Property 3 of consistency, it is hence clear that there exists a \( q \in \mathbb{Q} \) as required.

We now define a solution for \( G' \). This success proves the theorem since, obviously, solutions for \( G' \) can straightforwardly be converted into solutions for \( G \).

Since \( G' \) does not contain a \( <\)-cycle, \( E' \) induces a partial order \( \prec \) with domain \( V' \) such that \( v_1 \prec v_2 \) if there exists a \( \prec \)-path from \( v_1 \) to \( v_2 \) in \( G' \). Let \( \ll \) be an enumeration of all nodes \( v \in V' \) such that, for all nodes \( v, v' \), the following property is satisfied: if

- there exists a \( q \in \mathbb{Q} \) such that \( =_q \in \tau'(v) \) and

- for all \( q \in \mathbb{Q} \), we have \( =_q \notin \tau'(v') \),

then \( v \ll v' \). Such an enumeration exists since \( V \) and thus also \( V' \) is countable. The mapping from \( V' \) to \( \mathbb{Q} \) is constructed by induction on \( \ll \) such that the following conditions are satisfied at every time during the construction: for all \( v, v_1, v_2 \in V' \), we have that

(I) \( v_1 \prec v_2 \) and \( (v_1), (v_2) \) defined implies \( (v_1) < (v_2) \) and

(II) \( v \) defined implies that \( (v) \) for all \( P_q' \in \tau'(v) \).

For the induction start, we set

\[
(v) := q \text{ iff } =_q \in \tau'(v) \text{ for all } v \in V'.
\]

This operation is well-defined since \( G' \) satisfies Property 2 of consistency which implies that, for every \( v \in V' \), there exist no \( q_1, q_2 \in \mathbb{Q} \) such that \( q_1 \neq q_2 \) and \( \{=_{q_1},=_{q_2}\} \subseteq \tau'(v) \). Moreover, (I) and (II) are satisfied:

- if \( v_1 \prec v_2 \), then there exists a \( \prec \)-path \( v_1, \ldots, v_k \) from \( v_1 \) to \( v_2 \), i.e. \( v_i' = v_1 \), \( v_k' = v_2 \), and \( (v_i,v_{i+1},\prec) \in E' \) for \( i < k \), recall that \( G' \) contains no \( =\)-edges”

Let \( (v_1) = q \) and \( (v_2) = q' \). By induction on \( k \), it is straightforward to show that \( >_q \in \tau'(v_i') \) for \( 0 < i < k \); for the induction step, \( =_q \in \tau'(v_i') \) and the fact that \( G' \) satisfies Properties 2 and 3 of normality and Property 3 of consistency yields \( >_q \in \tau'(v_i') \). The induction step is analogous. Hence, \( >_q \in \tau'(v_2) \). Since \( G' \) satisfies Property 2 of consistency, \( =_{q'} \in \tau'(v_2) \) and \( >_q \in \tau'(v_2) \) imply \( q < q' \) what was to be shown.

- We make a case distinction according to the predicate \( P \). If \( =_q \in \tau'(v) \), then \( (v) = q \) by definition of \( \tau' \). Now let \( <_q \in \tau'(v) \). If \( (v) \) is defined, then there exists some \( q' \in \mathbb{Q} \) such that \( =_{q'} \in \tau'(v) \). Since \( G' \) satisfies Property 2 of consistency, we have \( =_{q'} \in \tau'(v) \). The case \( >_q \in \tau'(v) \) is analogous.
Now for the induction step. Fix a \( v \in V' \) such that \( (v) \) is undefined and \( (v') \) is defined for all \( v' \) with \( v' \ll v \). Define four sets as follows:

\[
\Gamma_1 := \{ (v') \mid v' \in V, v' \ll v \text{ and } v' \prec v \} \\
\Gamma_2 := \{ q \mid q \succ q \in \tau(v) \} \\
\Gamma_3 := \{ (v') \mid v' \in V, v' \ll v \text{ and } v \prec v' \} \\
\Gamma_4 := \{ q \mid q \prec q \in \tau(v) \}
\]

Moreover, set \( \Gamma_\prec := \Gamma_1 \cup \Gamma_2 \) and \( \Gamma_\succ := \Gamma_3 \cup \Gamma_4 \). We distinguish four cases:

1. \( \Gamma_\succ \) and \( \Gamma_\prec \) are both empty. Then set \( (v) \) to some arbitrary \( q \in \mathbb{Q} \).

2. \( \Gamma_\succ = \emptyset \) and \( \Gamma_\prec \neq \emptyset \). Since \( \mathbb{Q} \) has no maximum and \( \Gamma_\prec \) is finite, there exists a \( q \in \mathbb{Q} \) such that \( q > \max(\Gamma_\prec) \). Set \( (v) := q \).

3. \( \Gamma_\succ \neq \emptyset \) and \( \Gamma_\prec = \emptyset \). Since \( \mathbb{Q} \) has no minimum and \( \Gamma_\succ \) is finite, there exists a \( q \in \mathbb{Q} \) such that \( q < \min(\Gamma_\succ) \). Set \( (v) := q \).

4. \( \Gamma_\succ \neq \emptyset \) and \( \Gamma_\prec \neq \emptyset \). We will show that \( \max(\Gamma_\prec) < \min(\Gamma_\succ) \). By density of \( \mathbb{Q} \), it then follows that there exists a \( q \in \mathbb{Q} \) such that \( \max(\Gamma_\prec) < q < \min(\Gamma_\succ) \). We set \( (v) := q \). To show that \( \max(\Gamma_\prec) < \min(\Gamma_\succ) \), we need to prove that \( q_1 \in \Gamma_i \) and \( q_2 \in \Gamma_j \) implies \( q_1 < q_2 \) for \( i, j \in \{(1, 3), (1, 4), (2, 3), (2, 4)\} \):

- \( i = 1 \) and \( j = 3 \). Then there exist \( v_1, v_2 \in V' \) such that \( v_1 \ll v, v_2 \ll v, v_1 \prec v, v_2 \prec v, q_1 = (v_1), \) and \( q_2 = (v_2) \). Clearly, \( v_1 \prec v \) and \( v_2 \prec v \) implies \( v_1 \prec v_2 \). Since Property (I) is satisfied, we have \( (v_1) < (v_2) \).

- \( i = 1 \) and \( j = 4 \). Then there exists a \( v' \) such that \( v' \ll v, v' \prec v, q_1 = (v'), \) and \( q_2 = (v_2) \). Since \( v' \prec v \), there exists a \( <\)-path \( v_0, \ldots, v_k \) from \( v' \) to \( v \), i.e., \( v_0 = v', v_k = v, \) and \( (v_i, v_{i+1}, <) \in E' \) for \( i < k \). By induction on \( k \), it is straightforward to prove that \( q_2 \in \tau(v_0) \): for the induction start, \( q_2 \in \tau(v_k) \) and \( (v_{k-1}, v_k, <) \in E' \) implies \( q_2 \in \tau(v_{k-1}) \) since \( G' \) satisfies Properties 2 and 3 of normality and Property 3 of consistency. The induction step is identical. Hence, \( q_2 \in \tau(v') \). Since \( G' \) satisfies Property (II) and \( q_1 = (v') \), we thus have \( q_1 < q_2 \).

- \( i = 2 \) and \( j = 3 \). Analogous to the previous case.

- \( i = 2 \) and \( j = 4 \). Then we have \( q_1 < q_2 \) by Property (II).

It is straightforward to check that the induction step preserves Properties (I) and (II). Moreover, the fact that \( G' \) satisfies Properties (I) and (II) clearly implies that \( G' \) is a solution for \( G' \) (again note that \( G' \) contains no “\( =\)-edges”).

It is interesting to note that Theorem 3.7 also holds if satisfiability over \( \mathbb{R} \) is considered instead of satisfiability over \( \mathbb{Q} \) (the same proof works). However, as noted in [15], Theorem 3.7 does not hold if satisfiability over non-dense structures such as \( \mathbb{N} \) is considered. We will return to this issue in Section 7.

Intuitively, every constraint graph \( G = (V, E, \tau) \) can be converted into a normal one (called a normalization of \( G \)) by first specializing the relations in \( E \) and \( \tau \) such that Conditions 1 and 2 of normality are satisfied and then augmenting \( \tau \) such that Condition 3 holds.
Definition 3.8 (Normalization). A constraint graph $G = (V, E, \tau)$ is a normalization of the constraint graph $G' = (V, E', \tau')$ iff it is normal and the following conditions are satisfied:

1. $(v_1, v_2, P) \in E'$ with $P \in \{<, =\}$ implies $(v_1, v_2, P) \in E$,
2. $(v_1, v_2, >) \in E'$ implies $(v_2, v_1, <) \in E$,
3. $(v_1, v_2, \leq) \in E'$ implies $\{(v_1, v_2, <), (v_1, v_2, =)\} \cap E \neq \emptyset$,
4. $(v_1, v_2, \geq) \in E'$ implies $\{(v_2, v_1, <), (v_1, v_2, =)\} \cap E \neq \emptyset$,
5. $(v_1, v_2, \neq) \in E'$ implies $\{(v_1, v_2, <), (v_2, v_1, <)\} \cap E \neq \emptyset$,
6. if $(v, P_q) \in \tau$, then there exists a $v' \in V$ and a $P'$ such that $(v', P'_q) \in \tau'$,
7. $(v, P_q) \in \tau'$ with $P \in \{<, =, >\}$ implies $(v, P_q) \in \tau$,
8. $(v, \leq_q) \in \tau'$ implies $\{(v, <_q), (v, =_q)\} \cap \tau \neq \emptyset$,
9. $(v, \geq_q) \in \tau'$ implies $\{(v, >_q), (v, =_q)\} \cap \tau \neq \emptyset$, and
10. $(v, \neq_q) \in \tau'$ implies $\{(v, <_q), (v, >_q)\} \cap \tau \neq \emptyset$.

\[\diamond\]

4 Defining Hintikka-trees

In this section, we define Hintikka-trees, which are, as has already been noted, abstractions of canonical tree-models. Let us start with defining, for each concept $C$ and role hierarchy $\mathcal{R}$, the set of concepts $\text{cl}(C, \mathcal{R})$ that are “relevant” for deciding whether a given interpretation is a model of $C$ and $\mathcal{R}$: for a given concept $C$ and role hierarchy $\mathcal{R}$, we use $\text{cl}(C, \mathcal{R})$ to denote the smallest set such that

1. $C \in \text{cl}(C, \mathcal{R})$,
2. $\top \in \text{cl}(C, \mathcal{R})$,
3. if $\forall R. D \in \text{cl}(C, \mathcal{R})$, $\text{Trans}(S)$, and $S \sqsubseteq R$, then $\forall S. D \in \text{cl}(C, \mathcal{R})$, and
4. $\text{cl}(C, \mathcal{R})$ is closed under subformulas and $\sim$ (c.f. Definition 3.1).

Note that $\xi \text{cl}(C, \mathcal{R})$ is polynomial in the length of $C$ and the number of role inclusions in $\mathcal{R}$.

Hintikka-trees are defined in several steps. We start with introducing Hintikka-sets, which form the basis for the definition of so-called Hintikka-labels. As the name indicates, Hintikka-labels are used as node labels in Hintikka-trees. We then define Hintikka-tuples, which are tuples of Hintikka-labels that describe a valid label configuration for a node and its direct successors in a Hintikka-tree (Hintikka-tuples will also be rather convenient for defining looping automata that accept Hintikka-trees). Eventually, we use Hintikka-labels and Hintikka-tuples to define Hintikka-trees.
Intuitively, each node $\alpha$ of a Hintikka-tree $T$ describes a domain element $x$ of the corresponding canonical model $I$. The node label of $\alpha$ consists of several parts, one of them a Hintikka-set. This Hintikka-set contains all concepts $D$ from $\operatorname{cl}(C, \mathcal{R})$ such that $x \in D^x$.

**Definition 4.1 (Hintikka-set).** Let $C$ be a concept in PNF and $\mathcal{R}$ a role hierarchy. A set $\Psi \subseteq \operatorname{cl}(C, \mathcal{R})$ is a *Hintikka-set for $C$ and $\mathcal{R}$* iff it satisfies the following conditions:

(S1) if $C_1 \cap C_2 \in \Psi$, then $\{C_1, C_2\} \subseteq \Psi$,

(S2) if $C_1 \cup C_2 \in \Psi$, then $\{C_1, C_2\} \cap \Psi \neq \emptyset$,

(S3) $\{A, \neg A\} \not\subseteq \Psi$ for all concept names $A \in \operatorname{cl}(C, \mathcal{R})$,

(S4) if $f \in N_{\mathcal{R}}$ is used in $C$ or $\mathcal{R}$, then $(\leq 1 f \top) \in \Psi$,

(S5) if $(\leq n R D) \in \operatorname{cl}(C, \mathcal{R})$, then $\{D, \neg D\} \cap \Psi \neq \emptyset$,

(S6) $\top \in \Psi$

Concepts of the form $\exists R.D, (\geq n R D), (\leq n R D)$, and $\exists R g_1, g_2 P$ may appear either marked or unmarked in $\Psi$. 

The marking of concepts is a technical trick that allows us to deal with the inverse role constructor. Intuitively, edges of a Hintikka-tree $T$ describe role successor relationships of the corresponding canonical model $I$. If $\exists R D$ occurs in the Hintikka-set of a node $\beta$, then there has to exist a “witness” for this concept: either (i) there exists a successor $\gamma$ of $\beta$ such that the edge from $\beta$ to $\gamma$ represents an $R$ role relationship and $D$ is in the Hintikka-set of $\gamma$, or (ii) $\beta$ has a predecessor $\alpha$, the edge from $\alpha$ to $\beta$ represents an $\lnv(R)$ role relationship, and $D$ occurs in the Hintikka-set of $\alpha$. The marking of concepts is used for bookkeeping of these two possibilities: if $\exists R D$ occurs marked in the Hintikka-set of $\beta$, then $\alpha$ is a “witness” for $\exists R D$ and we do not need to enforce the existence of a witness among $\beta$’s successors. The marking of $(\geq n R D)$, $(\leq n R D)$, and $\exists R g_1, g_2 P$ concepts can be explained similarly. Hintikka-sets are one of the components of Hintikka-labels:

**Definition 4.2 (Hintikka-label).** Let $C$ be a concept in PNF and $\mathcal{R}$ a role hierarchy. A *Hintikka-label* $(\Psi, \omega, V, E, \tau)$ for $C$ and $\mathcal{R}$ consists of

1. a Hintikka-set $\Psi$ for $C$ and $\mathcal{R}$,

2. a set $\omega \subseteq \operatorname{ROL}$ of roles occurring in $C$ or $\mathcal{R}$, and

3. a constraint graph $(V, E, \tau)$ where $V \subseteq N_{\mathcal{R}}$, every $g \in V$ occurs in $C$, and every $g$ appearing in $\tau$ occurs in $C$.

such that

(N1) if $\exists g_1, g_2 P \in \Psi$, then $g_1, g_2 \in V$ and $(g_1, g_2, P) \in E$,

(N2) if $\forall g_1, g_2 P \in \Psi$ and $g_1, g_2 \in V$, then $(g_1, g_2, P) \in E$,
(N3) if \( g.P_q \in \Psi \), then \( g \in V \) and \( (g.P_q) \in \tau \),

(N4) \( R \in \omega \) and \( R \not\subseteq S \) implies \( S \in \omega \),

(N5) if \( g_1, g_2 \in V \), then \( \{(g_1, g_2, <), (g_1, g_2, =), (g_2, g_1, <)\} \cap E \neq \emptyset \), and

(N6) if \( q \) appears in \( C \), then, for each \( g' \in V \), there exists a \( P' \in \{<, =, >\} \) such that

\( (g', P'_q) \in \tau \).

The set of all Hintikka-labels for \( C \) and \( \mathcal{R} \) is denoted by \( \Gamma_{C, \mathcal{R}} \).

Let us explain the intuition behind Hintikka-labels. If \( \alpha \) is a node in a Hintikka-tree \( T \), \( \mathcal{I} \) the canonical model corresponding to \( T \), and \( x \in \Delta_\mathcal{I} \) the domain element associated with \( \alpha \), then the Hintikka-label \( L = (\Psi, \omega, V, E, \tau) \) of \( \alpha \) is a description of \( x \) in \( \mathcal{I} \). More precisely, (i) the Hintikka-set \( \Psi \) is the set of concepts \( D \in \text{cl}(C, \mathcal{R}) \) such that \( x \in D^2 \) (ii) \( \omega \) is the set of roles \( R \in \text{ROL} \) such that \( (y, x) \in R^2 \), where \( y \) is the domain element corresponding to the predecessor \( \beta \) of \( \alpha \) in \( T \); and (iii) the constraint graph \( (V, E, \tau) \) describes the numerical successors of \( x \) and their relationships: if, for some \( g \in \text{Rev} \), we have \( g \in V \), then \( g^2(x) \) is defined. By (N5) and (N6), \( (V, E, \tau) \) fixes the relationship between any two numerical successors of \( x \) as well as the relationship between any numerical successor of \( x \) and any rational number \( q \) appearing in the input concept. By (N1), (N2), and (N3), the relationships stated by \( E \) and \( \tau \) are “consistent” with the Hintikka-set \( \Psi \).

It is rather important that the constraint graph \( (V, E, \tau) \) fixes the relationship between any two nodes of \( V \): as already noted in Section 3, every Hintikka-tree \( T \) induces a (normal) constraint graph \( G(T) \) that describes the “numerical part” of the canonical interpretation corresponding to \( T \), and should thus be satisfiable. Since \( G(T) \) is normal, by Theorem 3.7 it suffices to demand that \( G(T) \) should be consistent. The complete determination of the relationships between nodes of the constraint graphs \( (V, E, \tau) \) in Hintikka-labels will allow us to ensure the consistency of \( G(T) \) using a local condition which can be verified by looping automata. This condition is part of the definition of Hintikka-tuples, which are introduced next.

**Definition 4.3 (Tuple-graph, Hintikka-tuple).** Let \( C \) be a concept in PNF and \( \mathcal{R} \) a role hierarchy. With \( b_{C, \mathcal{R}} \), we denote

\[
\#\{ D \in \text{cl}(C, \mathcal{R}) \mid D = \exists R.E \text{ or } D = \exists Rg_1, g_2, P \} + \sum_{(\geq n \ R \ C) \in \text{cl}(C, \mathcal{R})} n.
\]

Let \( \chi = (L_0, \ldots, L_{b_{C, \mathcal{R}}} \) be an \( b_{C, \mathcal{R}}+1 \)-tuple of Hintikka-labels with \( L_i = (\Psi_i, \omega_i, V_i, E_i, \tau_i) \) for \( i \leq b_{C, \mathcal{R}} \). A constraint graph \( G = (V, E, \tau) \) is a *tuple-graph* for \( \chi \) if

\[
\begin{align*}
V & = V_0 \cup \{ i g \mid 1 \leq i \leq b_{C, \mathcal{R}} \text{ and } g \in V_i \} \\
E & \supseteq E_0 \cup \{ (i g_1, i g_2, P) \mid 1 \leq i \leq b_{C, \mathcal{R}} \text{ and } (g_1, g_2, P) \in E_i \} \\
\tau & = \tau_0 \cup \{ (i g, P_q) \mid 1 \leq i \leq b_{C, \mathcal{R}} \text{ and } (g, P_q) \in \tau_i \}
\end{align*}
\]

such that

17
(G1) if \( \exists R, g, g'. P \) is unmarked in \( \Psi_0 \), then there exists an \( i \) with \( 1 \leq i \leq b_{C, R} \) such that \( ig, g' \in V, R \in \omega_i \), and \( (ig, g', P) \in E \).

(G2) if \( \exists R, g, g'. P \) is marked in \( \Psi_i \) with \( 1 \leq i \leq b_{C, R} \), then \( g, ig' \in V, \lnv(R) \in \omega_i \), and \((g, ig', P) \in E \).

(G3) if \( \forall R, g, g'. P \in \Psi_0, R \in \omega_i, g \in V_i \), and \( g' \in V_0 \) for some \( i \) with \( 1 \leq i \leq b_{C, R} \), then \((g, \lnv(R), P) \in E \).

(G4) if \( \forall R, g, g'. P \in \Psi_i, \lnv(R) \in \omega_i, g \in V_0 \), and \( g' \in V_i \) for some \( i \) with \( 1 \leq i \leq b_{C, R} \), then \((g, \lnv(R), P) \in E \).

The tuple \( \chi \) is a Hintikka-tuple iff the following conditions are satisfied:

(M1) if \( \exists R, D \) is unmarked in \( \Psi_0 \), then there exists an \( i \) with \( 1 \leq i \leq b_{C, R} \) such that \( R \in \omega_i \) and \( D \in \Psi_i \).

(M2) if \((\geq n R, D) \in \Psi_0 \), then either

- \((\geq n R, D) \) is unmarked in \( \Psi_0 \) and there exists a set \( I \subseteq \{1, \ldots, b_{C, R} \} \) of cardinality \( n \) such that, for each \( i \in I \), we have \( R \in \omega_i \) and \( D \in \Psi_i \) or

- \((\geq n R, D) \) is marked in \( \Psi_0 \) and there exists a set \( I \subseteq \{1, \ldots, b_{C, R} \} \) of cardinality \( n - 1 \) such that, for each \( i \in I \), we have \( R \in \omega_i \) and \( D \in \Psi_i \).

(M3) if \( \exists R, D \) or \((\geq n R, D) \) is marked in \( \Psi_i \) with \( 1 \leq i \leq b_{C, R} \), then \( \lnv(R) \in \omega_i \) and \( D \in \Psi_0 \).

(M4) if \( \forall R, D \in \Psi_0 \) and \( R \in \omega_i \) with \( 1 \leq i \leq b_{C, R} \), then \( D \in \Psi_i \).

(M5) if \( \forall R, D \in \Psi_i \) and \( \lnv(R) \in \omega_i \) with \( 1 \leq i \leq b_{C, R} \), then \( D \in \Psi_0 \).

(M6) if \( \forall R, D \in \Psi_0, S \in \omega_i \) with \( 1 \leq i \leq b_{C, R} \), then \( S \subseteq R \), and \( S \subseteq R \), then \( \forall S, D \in \Psi_i \).

(M7) if \( \forall R, D \in \Psi_i \) and \( \lnv(S) \in \omega_i \) with \( 1 \leq i \leq b_{C, R} \), then \( S \subseteq R \), and \( S \subseteq R \), then \( \forall S, D \in \Psi_0 \).

(M8) if \((\leq n R, D) \) is unmarked in \( \Psi_0 \), then either

- \((\leq n R, D) \) is unmarked in \( \Psi_0 \) and the cardinality of the set \( \{i \mid 1 \leq i \leq b_{C, R}, R \in \omega_i \} \) is at most \( n \) or

- \((\leq n R, D) \) is marked in \( \Psi_0 \) and the cardinality of the set \( \{i \mid 1 \leq i \leq b_{C, R}, R \in \omega_i \} \) is at most \( n - 1 \).

(M9) if \( D \in \Psi_0 \), \( \lnv(R) \in \omega_i \), and \((\leq n R, D) \) is marked in \( \Psi_i \) for \( 1 \leq i \leq b_{C, R} \), then \((\leq n R, D) \) is marked in \( \Psi_i \).

(M10) there exists a tuple-graph for \( \chi \) that has a consistent normalization. \( \diamond \)
Except for (M10), which refers to tuple-graphs and is the aforementioned local condition enforcing consistency of induced constraint graphs, the properties of Hintikka-tuples should be quite easy to understand. Before we discuss tuple graphs and (M10) in more detail, let us introduce Hintikka-trees.

**Definition 4.4 (Hintikka-tree).** An \( b_{C,R} \)-ary \( \Gamma_{C,R} \)-tree \( T \) with \( T(c) = (\Psi, \omega, V, E, \tau) \) is a Hintikka-tree for \( C \) and \( R \) iff it satisfies the following conditions:

1. \( C \in \Psi, \)
2. all concepts in \( \Psi \) are unmarked, and
3. for all \( \alpha \in \{1, \ldots, b_{C,R}\}^*, \) the tuple \( (T(\alpha), T(\alpha_1), \ldots, T(ab_{C,R})) \) is a Hintikka-tuple.

Let \( T \) be a Hintikka-tree, \( \alpha \in \{1, \ldots, b_{C,R}\}^* \) a node in \( T \), and \( T(\alpha) = (\Psi, \omega, V, E, \tau) \). We use \( \Psi_T(\alpha) \) to denote \( \Psi \) and \( \omega_T \) to denote \( \omega \).

We can now return to the discussion of Property (M10). As is apparent from their definition, tuple-graphs are built by taking the union of all the constraint graphs that appear as a part of the Hintikka-labels in a Hintikka-tuple. The constraint graph \( G(T) \) induced by a Hintikka-tree \( T \), in turn, is constructed from tuple-graphs: by (T3), for each node \( \alpha \) of \( T \), the tuple

\[ \chi_T(\alpha) := (T(\alpha), T(\alpha_1), \ldots, T(ab_{C,R})) \]

is a Hintikka-tuple. By (M10), there exists a tuple-graph \( G_T(\alpha) \) for \( \chi_T(\alpha) \) which has a consistent normalization \( G_T^\alpha(\alpha) \). Modulo some technical details, the constraint graph \( G(T) \) induced by \( T \) can be viewed as the union of the constraint graphs \( G_T^\alpha(\alpha) \) for all nodes \( \alpha \) of \( T \). Figure 1 illustrates the relationship between the various constraint graphs involved. In the following section, we will prove that the consistency of the normalizations \( G_T^\alpha(\alpha) \) enforced by (M10) implies consistency of the constraint graph \( G(T) \). The hardest part of this proof is to show that \( G(T) \) satisfies Property 1 of consistency, i.e., that it contains no \( \prec \)-cycle: for this proof, it is crucial that

1. the tuple-graph \( G_T(\alpha) \) overlaps with the tuple-graph \( G_T(\beta) \) if \( \beta \) is a successor of \( \alpha \) in \( T \), and
2. the constraint graphs \( (V, E, \tau) \), which are part of Hintikka-tuples and thus used to build of tuple-graphs, fix the relationship between any two elements of \( V \) as discussed above.

Using the fact that the constraint graphs induced by Hintikka-trees are consistent, we can then show that Hintikka-trees are indeed proper abstractions of \( Q - \mathcal{SHIQ} \)-interpretations.
5 Correctness and Complexity

In this section, we show that Hintikka-trees are proper abstractions of models, i.e., that a concept $C$ and a role hierarchy $\mathcal{R}$ have a model iff $C$ and $\mathcal{R}$ have a Hintikka-tree. We start with formally defining the constraint graph $G(T)$ induced by the Hintikka-tree $T$.

**Definition 5.1 (Corresponding Constraint Graph).** Let $T$ be a Hintikka-tree. By Properties (T3) and (M10), for each node $\alpha$ in $T$, there exists a tuple-graph

$$G_T(\alpha) = (V_T(\alpha), E_T(\alpha), \tau_T(\alpha))$$

for the Hintikka-tuple $\{\alpha, \alpha_1, \ldots, \alpha_{b_{C,\mathcal{R}}}, \}$, and $G_T(\alpha)$ has a consistent normalization

$$G_T^\exists(\alpha) = (V_T^\exists(\alpha), E_T^\exists(\alpha), \tau_T^\exists(\alpha)).$$

We define a constraint graph $G(T)$ corresponding to $T$. Its nodes have the form $\alpha|v$, where $\alpha$ is a node in $T$ and $v \in V_T(\alpha)$. More precisely, $G(T)$ is defined as $(V, E, \tau)$, where

$$V := \bigcup_{\alpha \in \{1, \ldots, b_{C,\mathcal{R}}\}^*} \{\alpha|v \mid v \in V_T(\alpha)\}$$

$$E := \bigcup_{\alpha \in \{1, \ldots, b_{C,\mathcal{R}}\}^*} \{(\alpha|v, \alpha|v', P) \mid (v, v', P) \in E_T^\exists(\alpha)\}$$

$$\cup \bigcup_{\alpha \in \{1, \ldots, b_{C,\mathcal{R}}\}^*} \{\{\alpha|g, \alpha|g, = \mid ig \in V_T(\alpha)\}\}$$

$$\tau := \bigcup_{\alpha \in \{1, \ldots, b_{C,\mathcal{R}}\}^*} \{\{\alpha|v, P_q\} \mid (v, P_q) \in \tau_T^\exists(\alpha)\}\}$$

It is not hard to see that $G(T)$ is well defined: if $ig \in V_T(\alpha)$, then, by definition of tuple-graphs, we have $g \in V_T(\alpha)$.

We will use the naming conventions introduced in Definition 5.1 (i.e., $G_T(\alpha)$, $V_T(\alpha)$, $G_T^\exists(\alpha)$, etc.) throughout this section. Let us now establish a lemma that will be central for showing soundness, i.e., for showing that the existence of a Hintikka-tree for $C$ and $\mathcal{R}$ implies the existence of a model of $C$ and $\mathcal{R}$.
Lemma 5.2. For every Hintikka-tree $T$, the corresponding constraint graph $G(T)$ is satisfiable.

Proof By Theorem 3.7, it succeeds to show that $G(T)$ is normal and consistent. We start with normality, i.e., we show that the the corresponding Properties 1 to 3 from Definition 3.6 are satisfied:

1. Property 1 is satisfied by construction of $G(T)$ since all constraint graphs $G^n_T(\alpha)$ are normal.

2. Property 2 is satisfied for the same reasons.

3. Let $(\alpha|v, P_q, \alpha') \in \tau$ and $\alpha'|v' \in V$. We need to show that there exists a predicate $P^*_v \in \{<, =, >\}$ such that $(\alpha'|v', P^*_v) \in \tau$. By definition of $G(T)$, $v \in V_T(\alpha)$, $v' \in V_T(\alpha')$, and $(v, P_q, \alpha) \in \tau^T(\alpha)$. By Property 6 of normalizations, there exists a $v'' \in V_T(\alpha)$ and a $P^v$ such that $v'' \in V_T(\alpha')$ and $P^v' \in \tau^T(\alpha')$. By definition of tuple-graphs and Hintikka-labels, this implies that $q$ occurs in $C$. Since $v' \in V_T(\alpha')$, we can distinguish two cases by definition of tuple-graphs:

- $v' = q$ for some $q \in \mathbb{N}_F$. Then $v' \in V_T(\alpha')$, (N6), and the fact that $q$ occurs in $C$ imply that there exists a $P^*_v \in \{<, =, >\}$ such that $(q, P^*_v, \alpha) \in \tau(\alpha')$. By Definition 7 of normalizations, this implies $(q, P^*_v, \alpha') \in \tau^n_T(\alpha')$. By definition of $G(T)$, we have $(\alpha'|v', P^*_v) \in \tau$.

- $v' = ig$ for some $i \in \{1, \ldots, b_{C/\tau}\}$ and $g \in \mathbb{N}_F$. Then $v' \in V_T(\alpha')$ and the definition of tuple-graphs implies $g \in V_T(\alpha|v)$. By (N6), and the fact that $q$ occurs in $C$, this yields the existence of a $P^*_v \in \{<, =, >\}$ such that $(g, P^*_v, \alpha) \in \tau(\alpha|g)$. By definition of tuple-graphs, this implies $(g, P^*_v, \alpha') \in \tau(\alpha')$. Property 7 of normalizations yields $(ig, P^*_v) \in \tau^n_T(\alpha')$. By definition of $G(T)$ and since $v' = ig$, we obtain $(\alpha'|v', P^*_v) \in \tau$.

We now show that $G(T)$ is consistent, i.e., that it satisfies the corresponding Properties 1 to 3 from Definition 3.6. We start with the simpler Properties 2 and 3:

2. Let $\alpha|v \in V$. We need to show that there exists a $q \in \mathbb{Q}$ such that $qP_q^v$ for all $P_q^v \in \tau(\alpha|v)$. Since $G^n_T(\alpha)$ is normal and consistent, Theorem 3.7 implies that it is also satisfiable. Let be a solution for $G^n_T(\alpha)$ and set $q := (v)$. We show that $q$ is as required. Let $P_q^v \in \tau(\alpha|v)$. By definition of $G(T)$, we have $v \in V_T(\alpha)$ and $(v, P_q^v) \in \tau^n_T(\alpha)$. Since is a solution for $G^n_T(\alpha)$, we clearly have $(v) P_q^v$.

3. Let $\alpha_1|v_1, \alpha_2|v_2 \in V$ and $(\alpha_1|v_1, \alpha_2|v_2, P) \in E$. We need to show that there exist $q_1, q_2 \in \mathbb{Q}$ such that $q_1 P q_2, q_1 P q$ for all $P_q^v \in \tau(\alpha_1|v_1)$, and $q_2 P q$ for all $P_q^v \in \tau(\alpha_2|v_2)$. By definition of $G(T)$, we can make a case distinction as follows:

- $\alpha_1 = \alpha_2, v_1, v_2 \in V_T(\alpha_1)$, and $(v_1, v_2, P) \in E_T^+(\alpha_1)$. Since $G^n_T(\alpha_1)$ is normal and consistent, Theorem 3.7 implies that it is also satisfiable. Let be a solution for $G^n_T(\alpha_1)$ and set $q_1 := (v_1)$ and $q_2 := (v_2)$. We show that $q_1$ and $q_2$ are as required. Since $(v_1, v_2, P) \in E_T^+(\alpha_1)$ and is a solution for $G^n_T(\alpha_1)$, we clearly have $q_1 P q_2$. Now let $P_q^v \in \tau(\alpha_i|v_i)$ with $i \in \{1, 2\}$.
By definition of $G(T)$, we have $(v_i, P_q) \in \tau^n_T(\alpha_1)$. Since $P$ is a solution for $G^n_T(\alpha_1)$, this clearly implies $q_1Pq$.

- $\alpha_2 = \alpha_1i$, $v_1 = ig$, $v_2 = g$, $P$ is "=", and $ig \in V_T(\alpha_1)$. Since $G^n_T(\alpha_1)$ is normal and consistent, Theorem 3.7 implies that it is also satisfiable. Let be a solution for $G^n_T(\alpha_1)$ and set $q_1 := q_2 := (ig)$. We show that $q_1$ and $q_2$ are as required. Clearly, $q_1Pq_2$ is satisfied. Let $P'_q \in \tau(\alpha_1|v) = \tau(\alpha_1|ig)$. By definition of $G(T)$, we have $(ig, P'_q) \in \tau^n_T(\alpha_1)$. Since $\alpha_1$ is a solution for $G^n_T(\alpha_1)$, we have $q_1P'q$. Now let $P'_{q_2} \in \tau(\alpha_2|v_2) = \tau(\alpha_2i|g)$. By definition of $G(T)$, we have $(g, P'_{q_2}) \in \tau^n_T(\alpha_1i)$. In the following, we show that this implies $(ig, P'_{q_2}) \in \tau^n_T(\alpha_1i)$, which is clearly sufficient to prove that $q_2P'q$ since $q_2 = (ig)$ and $P$ is a solution for $G^n_T(\alpha_1)$. By Property 6 of normalizations and definition of tuple-graphs and Hintikka-tuples, $(g, P'_{q_2}) \in \tau^n_T(\alpha_1i)$ implies that $q$ occurs in $C$. Since $g \in V_T(\alpha_1i)$, this together with (N6) implies that there exists a $P^s \in \{<,=,>\}$ such that $(g, P^s_{q_2}) \in \tau_T(\alpha_1i)$. By Property 7 of normalizations, we obtain $(g, P^s_{q_2}) \in \tau^n_T(\alpha_1i)$. Since $G^n_T(\alpha_1i)$ is normal and consistent, $(g, P^s_{q_2}) \in \tau^n_T(\alpha_1i)$ and $(g, P^s_{q_2}) \in \tau^n_T(\alpha_1i)$ implies $P' = P^s$. Thus, $(g, P^s_{q_2}) \in \tau_T(\alpha_1i)$, which implies $(ig, P^s_{q_2}) \in \tau^n_T(\alpha_1)$ by definition of tuple-graphs and Hintikka-tuples and Property 7 of normalizations.

- $\alpha_1 = \alpha_2i$, $v_2 = ig$, $v_1 = g$, $P$ is "=", and $ig \in V_T(\alpha_2)$. Analogous to the previous case.

To show that $G(T)$ is consistent and thus satisfiable over $Q$, it remains to prove that Property 1 is satisfied. Assume to the contrary that $G(T)$ contains a $\prec$-cycle and that $O = \alpha_0v_0, \ldots, \alpha_nv_n$ is the $\prec$-cycle in $G(T)$ with minimal length. Fix a $t \leq n$ such that

for each $i$ with $i \leq n$ and each $\beta \in \{1, \ldots, b_C; R\}^+$, we have $\alpha_i \neq \alpha_i\beta$, (i)

i.e., there exist no $\alpha_i$ in $O$ such that $\alpha_i$ is a true prefix of $\alpha_i$ (such a $t$ exists since $O$ is of finite length). Since $O$ is a $\prec$-cycle, there exists an $s \leq n$ such that we have $(\alpha_s|v_s, \alpha_s|v_s, <) \in E$. We make a case distinction and derive a contradiction in either case.

- $\alpha_{s+1} = \alpha_s$. Define a sequence of nodes $O'$ from $O$ by deleting all nodes $\alpha_i|v_i$ with $\alpha_i = \alpha_s$. $O'$ is non-empty since $\alpha_s \neq \alpha_s$. We show that $O'$ is a $\prec$-cycle in $G(T)$ which is a contradiction to the minimality of $O$. Let $O' = \alpha_{s}^{|v_{s}}', \ldots, \alpha_m^{|v_{m}}'$. By definition of $G(T)$, the fact that $(\alpha_s|v_s, \alpha_{s+1}|v_{s+1}, <) \in E$ implies $\alpha_{s+1} = \alpha_s$. Since $\alpha_s \neq \alpha_s$, $\alpha_s|v_s$ and $\alpha_{s+1}|v_{s+1}$ are in $O'$ and it remains to show that $O'$ is a cycle in $G(T)$, i.e., for all $i \leq m$, we have $(\alpha_i^{|v_i}', \alpha_{i+1}^{|v_{i+1}}', P) \in E$ for some $P \in \{<,=\}$. Let $\alpha_i^{|v_i}'$ and $\alpha_{i+1}^{|v_{i+1}}'$ be nodes in $O'$. If these two nodes are already neighbor nodes in $O$, we are obviously done. Hence, assume that this is not the case. By construction of $O'$, this implies the existence of a path

$$a_{i}^{|v_{i}}, a_{i}^{|v_{i+1}}, \ldots, a_{i}^{|v_{s}}, a_{i+1}^{|v_{s+1}}$$

in $G(T)$ of length at most $n$. Since $\alpha_i^{|v_i} \neq \alpha_{i}^{|v_i}$ and $\alpha_{i+1}^{|v_{i+1}} \neq \alpha_{i}^{|v_i}$, by construction of $G(T)$ and by $(*)$, we have that

$$G^n_T(\alpha_i^{|v_i})$$

is consistent and satisfiable. Therefore, there exists a $\tau(\alpha_i^{|v_i})$ such that $(\alpha_i^{|v_i}', P) \in \tau(\alpha_i^{|v_i})$. Since $\alpha_i^{|v_i}'$ is a node in $O'$, this implies that $\alpha_i^{|v_i}' \in \tau^n_T(\alpha_i^{|v_i})$. By induction hypothesis, we conclude that $\alpha_i^{|v_i}' \in V_T(\alpha_i^{|v_i})$. This contradiction shows that $G(T)$ is consistent.
1. there exists a $\beta \in \{1, \ldots, b_{C, R}\}^*$ and a $j \in \{1, \ldots, b_{C, R}\}$ such that $\alpha_t = \beta j$
and $\alpha_t' = \alpha_t' = \beta$;
2. $v_i' = jg$, $v_i^* = g$, $v_z^* = g'$, and $v_i'^* = jg'$ for some $g, g' \in N_{C, F}$, and
3. $(\beta jg, \beta jg, =) \in E$ and $(\beta jg', \beta jg', =) \in E$.

By definition of $G(T)$, Point 3 implies $jg, jg' \in V_T(\beta)$. By (N5), and Property 1 of normalizations, this implies that either

(a) $(jg, jg', P) \in E_T(\beta) \cap E_T(\beta)$ for some $P \in \{<, \leq\}$ or
(b) $(jg', jg, <) \in E_T(\beta) \cap E_T(\beta)$.

First assume that (a) holds. Together with Point 1 and 2 and the definition of $G(T)$, $(jg, jg', P) \in E_T(\beta)$ obviously implies $(\alpha_t|v_i', \alpha_t'|v_i'^*, P) \in E$ and we are done. Moreover, case (b) leads to a contradiction, i.e., it cannot occur: by definition of tuple-graphs, $(jg', jg, <) \in E_T(\beta)$ implies $(g', g, <) \in E_T(\beta jg)$. By Property 1 of normalizations, we thus have $(g', g, <) \in E_T(\beta jg)$. By definition of $G(T)$ and Point 1 and 2, this implies that $(\alpha_t|v_i', \alpha_t|v_i'^*, <) \in E$. Hence, the path $\alpha_t|v_i', \ldots, \alpha_t|v_i'^*$ is a $<$-cycle in $G(T)$ of length at least $n - 2$ which contradicts the minimality of $O$.

- $\alpha_1 = \alpha_t$. We first show that there exists a node $\alpha_1|v_z$ in $O$ such that $\alpha_1 \neq \alpha_t$. For suppose that no such node exists. Then, by definition of $G(T)$, $v_0, \ldots, v_n$ is a $<$-cycle in $G_T(\alpha_t)$. This, however, contradicts the fact that $G_T(\alpha_t)$ is consistent. Hence, we may conclude the existence of an $\alpha_1$ as above. Define a sequence of nodes $O'$ from $O$ by deleting all nodes $\alpha_i|v_i$ with $\alpha_i \neq \alpha_t$. $O'$ is non-empty since $\alpha_s = \alpha_t$. Moreover, $O'$ is shorter than $O$ due to the existence of $\alpha_1$. We show that $O'$ is a $<$-cycle in $G(T)$ which is a contradiction to the minimality of $O$. Let $O' = \alpha_1|v'_0, \ldots, \alpha_1|v'_m$. By definition of $G(T)$, the fact that $(\alpha_1|v'_0, \alpha_1|v'_1, \ldots, \alpha_1|v'_m) \in E$ implies $\alpha_1|v'_0 = \alpha_1 = \alpha_t$. Hence, it remains to show that $O'$ is a cycle in $G(T)$, i.e., that, for all $i \leq m$, we have $(\alpha_1|v'_i, \alpha_1|v'_i, P) \in E$ for some $P \in \{<, \leq\}$.

Let $\alpha_t|v'_i$ and $\alpha_t|v'_i$ be nodes in $O'$. If these two nodes are already neighbor nodes in $O$, we are obviously done. Hence, assume that this is not the case. By construction of $O'$, this implies the existence of a path

$$\alpha_t|v'_i, \alpha_t|v'_i, \ldots, \alpha_t|v'_i, \alpha_t|v'_i$$

in $G(T)$ of length at most $n$ such that $\alpha_t^i \neq \alpha_t$ for $1 \leq i \leq x$. By construction of $G(T)$ and by (*), we have that

1. there exists a $\beta \in \{1, \ldots, b_{C, R}\}$ and a $j \in \{1, \ldots, b_{C, R}\}$ such that $\alpha_t = \beta j$
and $\alpha_t^i = \alpha_t^i = \beta$;
2. $v_i' = g, v_z^* = jg, v_z^* = g'$, and $v_i'^* = jg'$ for some $g, g' \in N_{C, F}$, and
3. $(\beta jg, \beta jg', =) \in E$ and $(\beta jg', \beta jg', =) \in E$.

By definition of $G(T)$ and by Point 3, both $jg$ and $jg'$ are nodes in $V_T(\beta)$. By (N5) and Property 1 of normalizations, this implies that either

---

23
(a) \((jg', jg, <) \in E_T(\beta) \cap E_T^n(\beta)\) or 
(b) \((jg, jg', P) \in E_T(\beta) \cap E_T^n(\beta)\) for some \(P \in \{<, =\}\).

Case (a) cannot occur: together with Point 1 and 2 and the definition of 
\(G(T)\), \((jg', jg, <) \in E_T^n(\beta)\) implies \((\alpha_t|v_i^n, \alpha_t^*|v_i^*, <) \in E\). Hence, the path \(\alpha_t^*|v_i^*, \ldots, \alpha_t^1|v_i^1\) is a \(<\)-cycle in \(G(T)\) of length at most \(n - 2\) which contradicts the minimality of \(O\). Hence, assume that (b) holds. By definition of tuple-graphs, \((jg, jg', P) \in E_T(\beta)\) implies \((g, g', P) \in E_T(\beta)\). By Property 7 of normalizations, this, in turn, implies \((g, g', P) \in E_T^n(\beta)\). By construction of \(G(T)\) and Point 1 and 2, we thus obtain \((\alpha_t|v_i^t, \alpha_t^1|v_i^1, P) \in E\) what was to be shown.

We can now prove soundness.

**Lemma 5.3.** If there exists a Hintikka-tree for a concept \(C\) in PNF and a role hierarchy \(\mathcal{R}\), then \(C\) is satisfiable w.r.t. \(\mathcal{R}\).

**Proof** Let \(C\) be a concept, \(\mathcal{R}\) a role hierarchy, and \(b_{C, \mathcal{R}}\) as in Definition 4.3. Moreover, let \(T\) be a Hintikka-tree for \(C\) and \(\mathcal{R}\). By Lemma 5.2, the corresponding constraint graph \(G(T) = (V, E, \tau)\) is satisfiable and thus has a solution \(\tau\). For each \(R \in \text{ROL}\), set 
\[ \mathcal{E}(R) = \{ (\alpha, \beta) \mid \beta = \alpha \tau \text{ and } R \in \omega_T(\beta) \} \cup \{ (\alpha, \beta) \mid \alpha = \beta \tau \text{ and } \text{inv}(R) \in \omega_T(\alpha) \} \]

We define an interpretation \(\mathcal{I} = (\Delta, \mathcal{A}, \mathcal{R})\) as follows:

\[
\Delta^\mathcal{I} = \{ 1, \ldots, b_{C, \mathcal{R}} \}^I \\
A^\mathcal{I} = \{ \alpha \mid A \in \Psi_T(\alpha) \} \text{ for all } A \in C_N \\
R^\mathcal{I} = \mathcal{E}(R) \cup \bigcup_{P \in R, \text{Trans}(P)} \mathcal{E}(P)^+ \text{ for all } R \in \mathbb{N}_R \\
g^\mathcal{I} = \{ (\alpha, x) \mid \alpha g \in V \text{ and } (\alpha g) = x \} \text{ for all } g \in \mathbb{N}_{CF}.
\]

Before we show that \(\mathcal{I}\) is well-defined, we establish a claim:

**Claim 1:** If \(R \in \text{ROL}\) is simple, then \(R^\mathcal{I} = \mathcal{E}(R)\).

Proof: If \(R \in \mathbb{N}_R\) is simple, then \(R^\mathcal{I} = \mathcal{E}(R)\) is an immediate consequence of the definition of \(R^\mathcal{I}\). Now let \(R = S^\sim\) be simple with \(S \in \mathbb{N}_R\). Then it is readily checked that \((S^-)^\mathcal{I} = (S^\mathcal{I})^- = \mathcal{E}(S^-) = \mathcal{E}(S^-)\).

We now show that \(\mathcal{I}\) is well-defined:

- For all \(R \in \mathbb{N}_R\), \(R^\mathcal{I}\) is transitive. Let \(\{(\alpha_1, \beta_1), (\alpha_2, \beta_2)\} \subseteq R^\mathcal{I}\) where \(\beta_1 = \alpha_2\). Then, for each \(i \in \{1, 2\}\), either (i) \((\alpha_i, \beta_i) \in \mathcal{E}(R)\) or (ii) there exists a role \(P_i\) such that \(P_i \not\subseteq R, \text{Trans}(P_i)\), and \((\alpha_i, \beta_i) \in \mathcal{E}(P_i)^+\). In Case (i), \((\alpha_i, \beta_i) \in \mathcal{E}(R)^+\) implies \((\alpha_i, \beta_i) \in \mathcal{E}(R)^+\) by \(\text{(N4)}\) and definition of \(\mathcal{E}\). Hence, \(\{(\alpha_1, \beta_1), (\alpha_2, \beta_2)\} \subseteq \mathcal{E}(R)^+\) which obviously implies \((\alpha_1, \beta_2) \in \mathcal{E}(R)^+\). Since \(R \not\subseteq R\) and \(\text{Trans}(R)\), we have \(\mathcal{E}(R)^+ \subseteq R^\mathcal{I}\) and thus \((\alpha_1, \beta_2) \in R^\mathcal{I}\).
• For all \( f \in \mathbb{N}_F \), \( f^\mathcal{I} \) is functional. For assume to the contrary that, for some \( f \in \mathbb{N}_F \), we have \( \{(\alpha, \beta_1), (\alpha, \beta_2)\} \subseteq f^\mathcal{I} \) with \( \beta_1 \neq \beta_2 \). By assumption (c.f. Section 3.1), \( f \) is simple. Thus, Claim 1, the non-emptyness of \( f^\mathcal{I} \), and the definition of \( \mathcal{E} \) and of Hintikka-tuples imply that \( f \) occurs in \( C \) or \( R \). Moreover, Claim 1 clearly implies that \( \{(\alpha, \beta_1), (\alpha, \beta_2)\} \subseteq \mathcal{E}(f) \). By (S4) and since \( f \) occurs in \( C \) or \( R \), we have \( (\leq 1 \ f \ T) \in \Psi_T(\alpha) \). We distinguish two cases: either there exists a \( j \in \{1, 2\} \) such that \( \alpha = \beta_j \) and \( \text{Inv}(f) \in \omega_T(\alpha) \) (for some \( i \)) or (ii) no such \( j \) exists. In Case (i), \( (\leq 1 \ f \ T) \) is marked in \( \Psi_T(\alpha) \) by (S6) and (M9). Thus, by (M8) and (S6) there exists no \( i \) such that \( f \in \omega_T(\alpha_i) \). Since \( T \) is a tree, this is a contradiction to the fact that \( (\alpha, \beta_j) \in \mathcal{E}(f) \), where \( \ell \in \{1, 2\} \) such that \( \ell \neq j \). In Case (ii), there clearly exist \( i_1 \) and \( i_2 \) such that \( \beta_j = \alpha i_j \) and \( f \in \omega_T(\beta_j) \) for \( j \in \{1, 2\} \). Since \( \beta_1 \neq \beta_2 \), we have \( i_1 \neq i_2 \). This, however, is a contradiction to (M8), (S6), and the fact that \( (\leq 1 \ f \ T) \in \Psi_T(\alpha) \).

• For all \( g \in \mathbb{N}_F \), \( g^\mathcal{I} \) is obviously functional.

We now prove that \( \mathcal{I} \) is a model of \( \mathcal{R} \). Hence, let \( R \subseteq S \) and \( (\alpha, \beta) \in R^\mathcal{I} \). Then either (i) \( (\alpha, \beta) \in \mathcal{E}(R) \) or (ii) there exists a role \( P \) such that \( P \in R \), \( \text{Trans}(P) \), and \( (\alpha, \beta) \in \mathcal{E}(P)^+ \). In Case (i), the definition of \( \mathcal{E} \), (N4), and \( R \subseteq S \) yields \( (\alpha, \beta) \in \mathcal{E}(S) \subseteq S^\mathcal{I} \).

In Case (ii), we clearly have \( P \in S \) and thus \( (\alpha, \beta) \in S^\mathcal{I} \) by definition of \( S^\mathcal{I} \).

It remains to prove that there exists an \( \alpha \in \Delta^\mathcal{I} \) such that \( \alpha \in C^\mathcal{I} \). To do this, we prove the following claim:

**Claim 2:** \( D \in \Psi_T(\alpha) \) implies \( \alpha \in D^\mathcal{I} \) for all \( \alpha \in \Delta^\mathcal{I} \) and \( D \in \text{cl}(C, \mathcal{R}) \).

Proof: The claim is proved by induction on the norm \( \| \cdot \| \) of concepts \( D \) which is defined inductively as follows:

\[
\begin{align*}
\|A\| & := \|\neg A\| & := 0 & \text{for } A \in \mathbb{N}_C \\
\|C_1 \sqcap C_2\| & := \|C_1 \sqcup C_2\| & := 1 + \|C_1\| + \|C_2\| \\
\|\exists R \cdot D\| & := \|\forall R \cdot D\| & := 1 + \|D\| \\
\|\exists u_1, u_2 \cdot P\| & := \|\forall u_1, u_2 \cdot P\| & := 0 \\
\|\exists R_{g_1, g_2} \cdot P\| & := \|\forall R_{g_1, g_2} \cdot P\| & := 0 \\
\|\exists g \cdot P\| & := 0
\end{align*}
\]

First for the induction start, which splits into several subcases:

- **D** is a concept name. Immediate by definition of \( \mathcal{I} \).

- **D = \neg E.** Since \( C \) is in NNF and by definition of \( \text{cl}(\cdot) \), \( D \) is in NNF. Hence, \( E \) is a concept name. By definition of \( \mathcal{I} \) and since \( \Psi_T(\alpha) \) is a Hintikka-set and thus satisfies (S3), we have \( \alpha \in (\neg E)^\mathcal{I} \).

- **D = \exists U_1, U_2 \cdot P.** We distinguish three subcases:

  1. \( U_1 = g_1 \) and \( U_2 = g_2 \). By (N1) and definition of tuple-graphs, we have \( g_1, g_2 \in \mathcal{E}_T(\alpha) \) and \( (g_1, g_2, P) \in \mathcal{E}_T(\alpha) \). By Properties 1 to 5 of normalizations, this implies that there exists a \( P' \in \{<, =\} \) such that \( g_1P'g_2 \) implies
\( q_1 P q_2 \) for all \( q_1, q_2 \in \mathbb{Q} \) and \((g_1, g_2, P') \in E^n_T(\alpha)\). By definition of \(G(T)\), \(g_1, g_2 \in V_T(\alpha)\) and \((g_1, g_2, P') \in E^n_T(\alpha)\) implies that \(\alpha|g_1, \alpha|g_2 \in V \) and \((\alpha|g_1, \alpha|g_2, P') \in E\). By definition of \(I\), we have \(g_1^T(\alpha) = (\alpha|g_1)\) and \(g_2^T(\alpha) = (\alpha|g_2)\). Since \(\alpha\) is a solution for \(G(T)\) and \((\alpha|g_1)P' (\alpha|g_2)\) implies \(\alpha|g_1 \in V\), this yields \(\alpha \in (\exists g_1, g_2, P)^T\).

2. \(U_1 = Rg_1, U_2 = g_2, \) and \(\exists Rg_1, g_2, P\) is unmarked in \(\Psi_T(\alpha)\). By \(G1\) and since \(\exists Rg_1, g_2, P\) is unmarked, there exists an \(i\) such that \(ig_1, g_2 \in V_T(\alpha), R \in \omega_T(\alpha)\), and \((ig_1, g_2, P) \in E_T(\alpha)\). By Properties 1 to 5 of normalizations, this implies that there exists a \(P' \in \{<,=\}\) such that \(q_1 P' q_2\) implies \(q_1 P q_2\) for all \(q_1, q_2 \in \mathbb{Q} \) and \((q_1, q_2, P') \in E^n_T(\alpha)\). By definition of \(G(T)\), \(ig_1, g_2 \in V_T(\alpha)\) and \((ig_1, g_2, P') \in E^n_T(\alpha)\) yields \(\alpha|ig_1, \alpha|g_2 \in V \) and \((\alpha|ig_1, \alpha|g_2, P') \in E\). Moreover, \(ig_1 \in V_T(\alpha)\) implies \((\alpha|ig_1, \alpha|g_1, =) \in E\). By definition of \(I\) and since \(R \in \omega_T(\alpha)\), we have \(\alpha, \alpha \in R^T, g_1^T(\alpha) = (\alpha|ig_1) \in (Rg_1)^T(\alpha)\). Moreover, since \(\alpha\) is a solution for \(G(T)\) and \((\alpha|ig_1, \alpha|g_2, P') \in E\), we have \((\alpha|ig_1)P' (\alpha|g_2)\), which implies \((\alpha|ig_1)P (\alpha|g_2)\). Summing up, \((\alpha|ig_1) \in (Rg_1)^T(\alpha), g_2^T(\alpha) = (\alpha|g_2), \) and \((\alpha|ig_1)P (\alpha|g_2)\) yields \(\alpha \in (\exists Rg_1, g_2, P)^T\).

3. \(U_1 = Rg_1, U_2 = g_2, \) and \(\exists Rg_1, g_2, P\) is marked in \(\Psi_T(\alpha)\). By \(T2\), there exists a \(\beta\) such that \(\alpha = \beta i\). By \(G2\), we have \(g_1, g_2 \in V_T(\beta), \) \(\text{inv}(R) \in \omega_T(\alpha), \) and \((g_1, ig_2, P) \in V_T(\beta)\). By Properties 1 to 5 of normalizations, this implies that there exists a \(P' \in \{<,=\}\) such that \(q_1 P' q_2\) implies \(q_1 P q_2\) for all \(q_1, q_2 \in \mathbb{Q} \) and \((q_1, ig_2, P') \in E^n_T(\beta)\). By definition of \(G(T)\), \(g_1, ig_2 \in V_T(\beta)\) and \((g_1, ig_2, P') \in E^n_T(\beta)\) yields \(\beta|g_1, \beta|ig_2 \in V \) and \((\beta|g_1, \beta|ig_2, P') \in E\). By definition of \(I\) and since \(\text{inv}(R) \in \omega_T(\alpha)\), we have \((\alpha, \beta) \in R^T, g_1^T(\beta) = (\beta|g_1), \) and \(g_2^T(\alpha) = (\alpha|g_2)\). This implies \((\beta|g_1) \in (Rg_1)^T(\alpha)\). By definition of \(G(T)\), \(ig_2 \in V_T(\beta)\) implies \((\beta|ig_2, \alpha|g_2, =) \in E\). Since \(\alpha\) is a solution for \(G(T)\), we thus have \(g_2^T(\alpha) = (\beta|g_2)\). Moreover, since \((\beta|g_1, \beta|ig_2, P') \in E \) and is a solution for \(G(T)\), we have \((\beta|g_1)^T (\beta|ig_2)\) which implies \((\beta|g_1)P (\beta|ig_2)\). Summing up, \((\beta|g_1) \in (Rg_1)^T(\alpha), g_2^T(\alpha) = (\beta|g_2), \) and \((\beta|g_1)P (\beta|ig_2)\) yields \(\alpha \in (\exists Rg_1, g_2, P)^T\).

- \(D = \forall U_1, U_2, P\). Two subcases can be distinguished:

1. \(U_1 = g_1\) and \(U_2 = g_2\). If \(g_1^T(\alpha)\) or \(g_2^T(\alpha)\) is undefined, then \(\alpha \in (\bigcup g_1, g_2, P)^T\) is trivially satisfied. Hence assume that \(g_1^T(\alpha)\) and \(g_2^T(\alpha)\) are defined. By definition of \(I\), this implies that \(\alpha|g_1 \in V, g_1^T(\alpha) = (\alpha|g_1), \alpha|g_2 \in V,\) and \(g_2^T(\alpha) = (\alpha|g_2)\). By definition of \(G(T)\), \(\alpha|g_1, \alpha|g_2 \in V\) implies \(g_1, g_2 \in V_T(\alpha)\). By \(N2\) and construction of tuple-graphs, we thus have \((g_1, g_2, P) \in E_T(\alpha)\). By Properties 1 to 5 of normalizations, there exists a \(P' \in \{<,=\}\) such that \(q_1 P' q_2\) implies \(q_1 P q_2\) for all \(q_1, q_2 \in \mathbb{Q} \) and \((g_1, g_2, P') \in E^n_T(\alpha)\). The latter implies that \((\alpha|g_1, \alpha|g_2, P') \in E\). Since \(\alpha\) is a solution for \(G(T)\), we thus have \((\alpha|g_1)P' (\alpha|g_2)\) which yields
\[(\alpha | g_1)P (\alpha | g_2). \text{ Together } g_1^T(\alpha) = (\alpha | g_1) \text{ and } g_2^T(\alpha) = (\alpha | g_2), \text{ we obtain } \alpha \in (\forall g_1, g_2)P^T.\]

2. \(U_1 = Rg_1 \) and \(U_2 = g_2. \) Let \(x_1 \in (Rg_1)^T(\alpha) \) and \(x_2 \in g_2^T(\alpha). \) By definition of \(I, \) we have \(\alpha | g_2 \in V \) and \(x_2 = (\alpha | g_2). \) Since, by definition of \(Q-S\) \(H\) \(Q\)-concepts, \(R \) is simple, Claim 1 and the definition of \(E \) implies that one of the following two cases applies:

- There exists an \(i \in \{1, \ldots, b_{\mathcal{C}}\} \) such that \(\alpha | g_1 \in V, \) \(R \in \omega_T(\alpha) \) and \(x_1 = (\alpha | g_1). \) By definition of \(G(T), \) \(\alpha | g_1, \alpha | g_2 \in V \) implies \(g_1 \in V_T(\alpha) \) and \(g_2 \in V_T(\alpha). \) By (G3), we thus have \((i g_1, g_2, P') \in E_T(\alpha). \) By Properties 1 to 5 of normalizations, there exists a \(P' \in \{<, =\} \) such that \(g_1 P' g_2 \) implies \(g_1 P' g_2 \) for all \(g_1, g_2 \in \mathcal{Q} \) and \((i g_1, g_2, P') \in E_T(\alpha) \). The latter implies \((\alpha | i g_1, \alpha | g_2, P') \in E. \) By definition of \(G(T), i g_1 \in V_T(\alpha) \) implies \((\alpha | i g_1, \alpha | g_1, =) \in E. \) Since \(i \) is a solution for \(G(T) \) and \(x_1 = (\alpha | g_1), \) this yields \(x_1 = (\alpha | i g_1). \) Moreover, since \((\alpha | i g_1, \alpha | g_2, P') \in E, \) we have \((\alpha | i g_1)P' (\alpha | g_2) \) implying \((\alpha | i g_1)P (\alpha | g_2). \) Hence, \(x_1 P x_2. \)

- There exists a \(\beta \) such that \(\alpha = \beta i, \beta | g_1 \in V, \) \(\text{ Inv}(R) \in \omega_T(\alpha) \) and \(x_1 = (\beta | g_1). \) By definition of \(G(T), \) \(\beta | g_1, \alpha | g_2 \in V \) implies \(g_1 \in V_T(\beta) \) and \(g_2 \in V_T(\alpha). \) By (G4), we thus have \((g_1, i g_2) \in E_T(\beta). \) By Properties 1 to 5 of normalizations, there exists a \(P' \in \{<, =\} \) such that \(g_1 P' g_2 \) implies \(g_1 P' g_2 \) for all \(g_1, g_2 \in \mathcal{Q} \) and \((g_1, i g_2, P') \in E_T(\beta). \) The latter implies \((\beta | g_1, \beta | i g_2, P') \in E. \) By definition of \(G(T), i g_2 \in V_T(\beta) \) implies \((\beta | i g_2, \alpha | g_2, =) \in E. \) Since \(i \) is a solution for \(G(T) \) and \(x_2 = (\alpha | g_2), \) this yields \(x_2 = (\beta | i g_2). \) Moreover, since \((\beta | g_1, \beta | i g_2, P') \in E, \) we have \((\beta | g_1)P' (\beta | i g_2) \) implying \((\beta | g_1)P (\beta | i g_2). \) Hence, \(x_1 P x_2. \)

Since this holds independently of the choice of \(x_1 \) and \(x_2, \) we have \(\alpha \in (\forall Rg_1, g_2)P^T. \)

- \(D = \exists g.P_q. \) By (N3), this implies \(g \in V_T(\alpha) \) and \((g, P_q) \in \tau_T(\alpha). \) By Properties 7 to 10 of normalizations, there exists a \(P' \in \{<, =, >\} \) such that \(q' P' q \) implies \(q' P' q \) for all \(q' \in \mathcal{Q}, \) and \((g, P_q') \in \tau_T(\alpha). \) By definition of \(G(T), \) we have \(\alpha | g \in V \) and \((\alpha | g, P_q') \in \tau. \) By definition of \(T, \) \(\alpha | g \in V \) implies \(g^T(\alpha) = (\alpha | g). \) Since \(i \) is a solution for \(G(T) \) and \((\alpha | g, P_q') \in \tau, \) we have \((\alpha | g)P' q, \) which implies \((\alpha | g)P q. \) Summing up, we obtain \(\alpha \in (\exists g.P_q)^T. \)

For the induction step, we make a case distinction according to the topmost operator in \(D. \) Assume \(D \in \Psi_T(\alpha). \)

- \(D = C_1 \cap C_2 \) or \(D = C_1 \cup C_2. \) Straightforward by (S1) and (S2) of Hintikka-sets and by induction hypothesis.

- \(D = \exists R.E. \) We can distinguish two cases:

  1. \(D \) is unmarked in \(\Psi_T(\alpha). \) By (M1), there exists an \(i \) such that \(R \in \omega_T(\alpha i) \) and \(E \in \Psi_T(\alpha i). \) By definition of \(R^T, \) we have \((\alpha, \alpha i) \in R^T. \) By induction, we obtain \(\alpha i \in E^T. \) Thus, \(\alpha \in D^T. \)
2. $D$ is marked in $\Psi_T(\alpha)$. By (T2), there exists a $\beta$ such that $\alpha = \beta i$. By (M3), we have $\lnv(R) \in \omega(\alpha)$ and $E \in \Psi_T(\beta)$. By definition of $R^2$, we have $(\alpha, \beta) \in R^2$. By induction, we obtain $\beta \in E^2$. Thus, $\alpha \in D^2$.

- $D = \forall R. E$. Let $(\alpha, \beta) \in R^2$. By definition of $R^2$, one of the following to cases applies:

1. $(\alpha, \beta) \in \mathcal{E}(R)$. By definition of $\mathcal{E}$, this implies that there exists an $i$ such that either (i) $\beta = \alpha i$ and $R \in \omega_T(\beta)$ or (ii) $\alpha = \beta i$ and $\lnv(R) \in \omega_T(\alpha)$. In Subcase (i), (M4) yields $E \in \Psi_T(\beta)$. In Subcase (ii), (M5) yields $E \in \Psi_T(\beta)$.

2. there exists a role $P$ such that $P \subseteq R$, $\text{Trans}(P)$, and $(\alpha, \beta) \in \mathcal{E}(P)^+$. Then there exist $\alpha_0, \ldots, \alpha_k$ such that $\alpha = \alpha_0$, $\beta = \alpha_k$, and $(\alpha_i, \alpha_{i+1}) \in \mathcal{E}(P)$ for $i < k$. If $k = 1$, then the definition of $\mathcal{E}$ and (N4) yields $(\alpha, \beta) \in \mathcal{E}(R)$ and we can continue as in Case 1. Hence assume $k > 1$. Using the fact that $\forall R. E \in \Psi_T(\alpha_0)$, the definition of $\mathcal{E}$, (M6), and (M7), it is readily checked that $\forall P. E \in \Psi_T(\alpha_i)$ for all $i$ with $0 < i \leq k$. As in Case 1, we may now use the fact that $\forall P. E \in \Psi_T(\alpha_{k-1})$, the definition of $\mathcal{E}$, (M4), and (M5) to show that $E \in \Psi_T(\alpha_k) = \Psi_T(\beta)$. By induction, we obtain $\beta \in E^2$. Since this holds independently of the choice of $\beta$, we conclude $\alpha \in D^2$.

- $D = (\geq n \ R \ E)$. First assume that $D$ is unmarked in $\Psi_T(\alpha)$. By (M2), there exists a set $I \subseteq \{1, \ldots, b_{C,R}\}$ of cardinality $n$ such that, for each $i \in I$, we have $R \in \omega_T(\alpha i)$ and $E \in \Psi_T(\alpha i)$. By definition of $R^2$, we have $(\alpha, \alpha i) \in R^2$ for every $i \in I$. By induction, we obtain $\alpha i \in E^2$ for every $i \in I$. Thus, $\sharp\{\beta \mid (\alpha, \beta) \in R^2 \text{ and } \beta \in E^2\} \geq n$ and $\alpha \in D^2$.

Now assume that $D$ is marked in $\Psi_T(\alpha)$. By (M2), there exists a set $I \subseteq \{1, \ldots, b_{C,R}\}$ of cardinality $n - 1$ such that, for each $i \in I$, we have $R \in \omega_T(\alpha i)$ and $E \in \Psi_T(\alpha i)$. By (T2), there exists a $\beta$ such that $\alpha = \beta i$. By (M3), we have $\lnv(R) \in \omega_T(\alpha)$ and $E \in \Psi_T(\beta)$. The definition of $R^2$ implies that $(\alpha, \alpha i) \in R^2$ for every $i \in I$ and $(\alpha, \beta) \in R^2$. By induction, we obtain $\alpha i \in E^2$ for every $i \in I$ and $\beta \in E^2$. Since, clearly, $\beta \neq \alpha i$ for all $i \in I$, we thus have $\sharp\{\beta \mid (\alpha, \beta) \in R^2 \text{ and } \beta \in E^2\} \geq n$ and conclude $\alpha \in D^2$.

- $D = (\leq n \ R \ E)$. Since $R$ is simple by definition of $\mathcal{Q}$-$\mathcal{SH}$-$\mathcal{IQ}$-concepts, Claim 1 yields $R^2 = \mathcal{E}(R)$, i.e., the set $\{\beta \mid (\alpha, \beta) \in R^2 \text{ and } \beta \in E^2\}$, whose cardinality we must show to be at most $n$, can be written as the union of the following two sets:

\[
S_1 = \{\alpha i \mid R \in \omega_T(\alpha i) \text{ and } \alpha i \in E^2\}
\]

\[
S_2 = \{\beta \mid \alpha = \beta i, \lnv(R) \in \omega_T(\alpha), \text{ and } \beta \in E^2\}.
\]

First assume that $D$ is unmarked in $\Psi_T(\alpha)$. By (M9), this implies that either (i) $\alpha = \epsilon$, (ii) $\lnv(R) \notin \omega_T(\alpha)$ or (iii) $E \notin \Psi_T(\beta)$ where $\alpha = \beta i$. In all three cases, $S_2$ is empty: this is obviously true for (i) and (ii); in Case (iii), (S5) yields $\sim E \in \Psi_T(\beta)$, and by induction, we obtain $\beta \in (\sim E)^2$ implying $\beta \notin E^2$. By (M8), $\sharp S_1$ is bounded by $n$: (M8) yields

\[
\sharp\{\alpha i \mid R \in \omega_T(\alpha i) \text{ and } E \in \Psi_T(\alpha i)\} \leq n.
\]  

(*)

28
Now assume that \(\mathcal{I}S_1\) is greater than the cardinality of the set in the inequality (*) which implies that there exists an \(i\) such that \(E \notin \Psi_T(\alpha i)\) but \(\alpha i \in E^T\). By (S5), \(E \notin \Psi_T(\alpha)\) yields \(\sim E \in \Psi_T(\alpha i)\). From the induction hypothesis, we obtain \(\alpha i \in (\sim E)^T\), a contradiction. We thus conclude that \(\mathcal{I}S_1\) is bounded by \(n\) which yields \(\alpha \in D^T\).

Now assume that \(D\) is marked in \(\Psi_T(\alpha)\). Since \(T\) is a tree, we have \(\mathcal{I}S_2 \leq 1\). Similar to the unmarked case, we can use (M8) and (S5) to deduce that \(\mathcal{I}S_1 \leq n - 1\). We thus conclude \(\forall \{\beta \mid (\alpha, \beta) \in R^T \text{ and } \beta \in E^T\} \leq n\) and \(\alpha \in D^T\).

This completes the proof of the claim. Since \(C \in \Psi_T(e)\), it is an immediate consequence of Claim 2 that \(\mathcal{I}\) is a model of \(C\).

We now prove completeness.

**Lemma 5.4.** If a concept \(C\) in PNF is satisfiable w.r.t. a role hierarchy \(\mathcal{R}\), then there exists a Hintikka-tree for \(C\) and \(\mathcal{R}\).

**Proof** Let \(C\) be a concept, \(\mathcal{R}\) a role hierarchy, and \(b_{C,\mathcal{R}}\) as in Definition 4.3. Moreover, let \(\mathcal{I}\) be a model of \(C\) and \(\mathcal{R}\), i.e., \(\mathcal{I}\) is an interpretation such that there exists an \(x_{\text{root}} \in \Delta_{\mathcal{I}}\) with \(x_{\text{root}} \in C^T\) and we have \(R^T \subseteq S^T\) for all \(R \subseteq S \in \mathcal{R}\).

Before we define a Hintikka-tree \(T\) for \(C\) and \(\mathcal{R}\), we introduce two auxiliary functions: (i) for every \(x \in \Delta_{\mathcal{I}} \cup \{\emptyset\}\) and \(y \in \Delta_{\mathcal{I}}\), we set \(\mathcal{I}(x, y) := (\Psi, \omega, V, E, \tau)\), where

\[
\begin{align*}
\Psi & := \{D \in C(C, \mathcal{R}) \mid y \in D^T\} \\
V & := \{g \in N_{ef} \mid g \text{ occurs in } C \text{ and } g^T(y) \text{ defined}\} \\
\omega & := \begin{cases} \\
\{ \{R \mid R \text{ occurs in } C \text{ or } \mathcal{R} \text{ and } (x, y) \in R^T\} & \text{if } x \notin \emptyset \\
\emptyset & \text{otherwise} \\
\end{cases} \\
E & := \{(g_1, g_2, P) \mid g_1, g_2 \in V \text{ and } g_1^T(y) P g_2^T(y)\} \\
\tau & := \{(g, P_q) \mid g \in V, q \text{ occurs in } C, \text{ and } g^T(y) P q\}.
\end{align*}
\]

(ii) for every \(x \in \Delta_{\mathcal{I}}\), we fix a set \(W(x) \subseteq \Delta_{\mathcal{I}}\) of witnesses such that

1. if \(x \in (\exists R D)^T\), then there exists a \(y \in W(x)\) such that \((x, y) \in R^T\) and \(y \in D^T\),
2. if \(x \in (\geq n R D)^T\), then there exists a subset \(\{y_0, \ldots, y_{n-1}\} \subseteq W(x)\) such that \((x, y_i) \in R^T\) and \(y_i \in D^T\) for \(i < k\),
3. if \(x \in (\leq n R D)^T\), then \(\exists \{y \in W(x) \mid (x, y) \in R^T\text{ and } y \in D^T\} \leq n\),
4. if \(x \in (\exists R g_1, g_2, P)^T\), then there exists a \(y \in W(x)\) such that \((x, y) \in R^T\) and \(g_1^T(y) P g_2^T(x)\), and
5. the cardinality of \(W(x)\) is at most \(b_{C,\mathcal{R}}\).

Using the semantics of \(\mathcal{Q}\)-SHIQ-concepts and the definition of \(b_{C,\mathcal{R}}\), it is not hard to check that, for every \(x \in \Delta_{\mathcal{I}}\), such a set of witnesses does indeed exist.

We now inductively define a Hintikka-tree \(T\) for \(C\) and \(\mathcal{R}\), i.e., an \(b_{C,\mathcal{R}}\)-ary \(\Gamma_{C,\mathcal{R}}\)-tree that satisfies (T1) to (T3). To simplify the construction of \(T\), along with \(T\) we
define a mapping \( \pi \) from \( \{1, \ldots, b_{C, R}\}^* \) to \( \Delta_T \) that keeps track of the correspondence between nodes in \( T \) and elements of \( \Delta_T \).

For the induction start, set

\[
\begin{align*}
\pi(\epsilon) & := x_{\text{root}} \\
T(\epsilon) & := \mathcal{I}(\emptyset, x_{\text{root}})
\end{align*}
\]

where all concepts are unmarked in \( \Psi_T(\epsilon) \). Now for the induction step. Let \( \alpha \in \{1, \ldots, b_{C, R}\}^* \) be a word of minimal length such that \( \pi(\alpha) \) is defined and \( \pi(\alpha i) \) is undefined for all \( i \in \{1, \ldots, b_{C, R}\} \). Set \( S := W(\pi(\alpha)) \) if \( \pi(\alpha) = x_{\text{root}} \) and \( S := W(\pi(\alpha)) \setminus \{\pi(\beta)\} \) if \( \alpha = \beta i \). Moreover, let \( S = \{x_1, \ldots, x_n\} \). Then do the following:

1. For all \( i \leq n \), set \( \pi(\alpha i) := x_i \) and \( T(\alpha i) := \mathcal{I}(\pi(\alpha), x_i) \). A concept \( \exists R . E \), \( (\leq n \ R \ E) \), or \( (\geq n \ R \ E) \) is marked in \( \Psi_T(\alpha i) \) iff \( \text{Inv}(R) \in \omega_T(\alpha i) \) and \( E \in \Psi_T(\alpha) \). A concept \( \exists R g_1, g_2 . P \) is marked in \( \Psi_T(\alpha i) \) iff \( \text{Inv}(R) \in \omega_T(\alpha i) \) and \( g_2^T(\pi(\alpha)) P g_2^T(x_i) \).

2. For all \( i \) with \( n < i \leq b_{C, R} \), set \( \pi(\alpha i) := x_{\text{root}} \) and \( T(\alpha i) := \mathcal{I}(\emptyset, x_{\text{root}}) \). All concepts are unmarked in \( \Psi_T(\alpha i) \).

Clearly, \( T \) is a \( b_{C, R} \)-ary tree. To show that \( T \) is a Hintikka-tree for \( C \) and \( R \), we need to prove that \( T \) is a \( \Gamma_{C, R} \)-tree and that (T1) to (T3) are satisfied. To show that \( T \) is a \( \Gamma_{C, R} \)-tree, in turn, we must prove that every node label is a Hintikka-label: clearly, if \( T(\alpha) = (\Psi, \omega, V, E, \tau) \) for some node \( \alpha \), then \( \omega \) is a set of roles occurring in \( C \) or \( R \) and \( (V, E, \tau) \) is a constraint graph as required by Definition 4.3. It thus remains to show that \( \Psi \) is a Hintikka-set for \( C \) and \( R \), i.e., that it satisfies (S1) to (S6), and that \( T(\alpha) \) satisfies (N1) to (N6). Both tasks, however, are trivial using the definition of \( \mathcal{I}(x, y) \).

It thus remains to show that (T1) to (T3) are satisfied. This is easy for (T1) and (T2) using the definition of \( T(\epsilon) \). In order to show that (T3) is satisfied, we have to prove that, for all \( \alpha \in \{1, \ldots, b_{C, R}\}^* \), the tuple \( (T(\alpha), T(\alpha 1), \ldots, T(ab_{C, R})) \) is a Hintikka-tuple, i.e., that it satisfies conditions (M1) to (M10). Before we do this, let us state two properties that can easily be seen to hold by considering the definitions of \( \mathcal{I}(\cdot, \cdot) \), \( T \), and \( \pi \):

(a) for all \( \alpha \in \{1, \ldots, b_{C, R}\}^* \), we have \( \Psi_T(\alpha) = \{D \mid D \in \text{d}(C, R) \text{ and } \pi(\alpha) \in D^T\} \);

(b) for all \( \alpha \in \{1, \ldots, b_{C, R}\}^* \), we have \( \omega_T(\alpha i) = \{R \text{ occurs in } C \text{ or } R \text{ and } \pi(\alpha_i) \in R^T\} \).

We now show that conditions (M1) to (M10) are satisfied.

(M1) Let \( \exists R . D \in \Psi_T(\alpha) \). By (a), we have \( \pi(\alpha) \in (\exists R . D)^T \). Thus, by Property 1 of \( W(\cdot) \), there exists a \( y \in W(\pi(\alpha)) \) such that \( (\pi(\alpha), y) \in R^T \) and \( y \in D^T \). If \( \exists R . D \) is unmarked in \( \Psi_T(\alpha) \), then we either have (i) \( \pi(\alpha) = x_{\text{root}} \) (induction start or Case 2 of the induction step) or (ii) there exists a \( \beta \) such that \( \alpha = \beta i \) and we have either \( \text{Inv}(R) \notin \omega_T(\alpha) \) or \( D \notin \Psi_T(\beta) \). In Case (i), we clearly
have \(y \in S = W(\pi(\alpha))\) during the induction step generating successors for \(\alpha\). In Case (ii), we have \((\pi(\alpha), \pi(\beta)) \notin R^T\) or \(\pi(\beta) \notin D^T\) by (b) and (a). This implies \(y \neq \pi(\beta)\) and thus we have \(y \in S\) during the induction step generating successors for \(\alpha\) in both Case (i) and (ii). Hence, by construction of \(T\) there exists an \(i \in \{1, \ldots, b_{C,R}\}\) such that \(\pi(\alpha_i) = y, \ R \in \omega_T(\alpha_i), \) and \(D \in \Psi_T(\alpha_i)\).

(M2) Let \((\geq n \ R \ D) \in \Psi_T(\alpha)\). By (a), we have \(\pi(\alpha) \in (\geq n \ R \ D)^T\). Thus, by Property 2 of \(W(\cdot)\), there exists a subset \(\{y_0, \ldots, y_{n-1}\} \subseteq W(\pi(\alpha))\) such that \((\pi(\alpha), y_i) \in R^T\) and \(y_i \in D^T\) for \(i < k\). We can distinguish two cases:

1. \((\geq n \ R \ D)\) is unmarked in \(\Psi_T(\alpha)\). Then we have either (i) \(\pi(\alpha) = \pi_{\text{root}}\) or (ii) there exists a \(\beta\) such that \(\alpha = \beta i\) and we have either \(R \notin \omega_T(\alpha)\) or \(D \notin \Psi_T(\beta)\). Similar to the (M1) case, in both cases we have \(\{y_0, \ldots, y_{n-1}\} \subseteq S\) during the induction step generating successors for \(\alpha\). By construction of \(T\), this clearly implies

\[
\sharp\{i \in \{1, \ldots, b_{C,R}\}^* \mid R \in \omega_T(\alpha_i) \text{ and } D \in \Psi_T(\alpha_i)\} \geq n
\]

as required.

2. \((\geq n \ R \ D)\) is marked in \(\Psi_T(\alpha)\). Then there exists a \(\beta \in \{1, \ldots, b_{C,R}\}^*\) such that \(\lnv(R) \in \omega_T(\alpha)\) and \(D \in \Psi_T(\beta)\). Since we may or may not have \(\pi(\beta) \in W(\pi(\alpha))\), it is easy to see that

\[
\sharp\{y \in S \mid (\pi(\alpha), y) \in R^T \text{ and } y_i \in D^T\} \in \{n-1, n\}
\]

during the induction step generating successors for \(\alpha\). By construction of \(T\), we thus have

\[
\sharp\{i \in \{1, \ldots, b_{C,R}\}^* \mid R \in \omega_T(\alpha_i) \text{ and } D \in \Psi_T(\alpha_i)\} \geq n - 1
\]

as required.

(M3) Immediate from the construction of \(T\).

(M4) Let \(\forall R.D \in \Psi_T(\alpha)\) and \(R \in \omega_T(\alpha_i)\) for some \(i \in \{1, \ldots, b_{C,R}\}^*\). By (a) and (b), this implies \(\pi(\alpha) \in (\forall R.D)^T\) and \((\pi(\alpha), \pi(\alpha_i)) \in R^T\). By \(Q\text{-}\text{SHIQ}\) semantics, we have \(\pi(\alpha_i) \in D^T\). Again by (a), we obtain \(D \in \Psi_T(\alpha_i)\).

(M5) Let \(\forall R.D \in \Psi_T(\alpha)\) and \(\lnv(R) \in \omega_T(\alpha)\). Since \(\omega_T(\alpha) \neq \emptyset\), there exist \(\beta\) and \(i\) such that \(\alpha = \beta i\). By (a) and (b), \(\forall R.D \in \Psi_T(\alpha)\) and \(\lnv(R) \in \omega_T(\alpha)\) implies \(\pi(\alpha) \in (\forall R.D)^T\) and \((\pi(\alpha), \pi(\beta)) \in R^T\). By \(Q\text{-}\text{SHIQ}\) semantics, we have \(\pi(\beta) \in D^T\). Again by (a), we obtain \(D \in \Psi_T(\beta)\).

(M6) Let \(\forall R.D \in \Psi_T(\alpha)\), \(S \in \omega_T(\alpha_i)\) with \(1 \leq i \leq b_{C,R}\), \(\text{Trans}(S), \) and \(S \subseteq R\). We show that \(\pi(\alpha_i) \in (\forall S.D)^T\) which, by (a), implies \(\forall S.D \in \Psi_T(\alpha)\) what needs to be shown. To this end, assume \((\pi(\alpha), x) \in S^T\). By (b), \(S \in \omega_T(\alpha_i)\) implies \((\pi(\alpha), \pi(\alpha_i)) \in S^T\). Since \(\text{Trans}(S)\) holds, together with \((\pi(\alpha), x) \in S^T\) this implies \((\pi(\alpha), x) \in S^T \subseteq R^T\). By (a), \(\forall R.D \in \Psi_T(\alpha)\) implies \(\pi(\alpha) \in (\forall R.D)^T\). By \(Q\text{-}\text{SHIQ}\) semantics, we obtain \(x \in D^T\). Since this holds independently of the choice of \(x\), we conclude \(\pi(\alpha_i) \in (\forall S.D)^T\).
(M7) Let $\forall R.D \in \Psi_T(\alpha)$ and $\lnv(S) \in \omega_T(\alpha)$, $\text{Trans}(S)$, and $S \subseteq R$. Since $\omega_T(\alpha) \neq \emptyset$, there exist $\beta$ and $i$ such that $\alpha = \beta i$. We show that $\pi(\beta) \in \forall u. D$ which, by (a), implies $\forall S.D \in \Psi_T(\beta)$ what needs to be shown. Hence, assume $(\pi(\beta), x) \in S^T$. By (b), $\lnv(S) \in \omega_T(\alpha)$ implies $(\pi(\alpha), \pi(\beta)) \in S^T$. Since $\text{Trans}(S)$ holds, together with $(\pi(\beta), x) \in S^T$ this implies $(\pi(\alpha), x) \in S^T \subseteq R^T$. By (a), $\forall R.D \in \Psi_T(\alpha)$ implies $\pi(\alpha) \in (\forall R.D)^T$. By $\mathcal{Q}$-$\mathcal{SHIQ}$ semantics, we obtain $x \in D^T$. Since this holds independently of the choice of $x$, we conclude $\pi(\beta) \in (\forall S.D)^T$.

(M8) Let $(\leq n R D) \in \Psi_T(\alpha)$. By (a), we have $\pi(\alpha) \in (\leq n R D)^T$. Thus, Property 3 of $W(\pi(\alpha))$ yields $\sharp K \leq n$, where

$$ K := \{ y \in W(\pi(\alpha)) \mid (\pi(\alpha), y) \in R^T \text{ and } y \in D^T \} \leq n. $$

We make a case distinction as follows:

1. $(\leq n R D)$ is unmarked in $\Psi_T(\alpha)$. We clearly have $S \subseteq W(\pi(\alpha))$ during the induction step generating successors for $\alpha$. This obviously implies

$$ \{ y \in S \mid (\pi(\alpha), y) \in R^T \text{ and } y \in D^T \} \subseteq K. $$

It is easy to check that this, together with $\sharp K \leq n$, implies

$$ \sharp \{ i \in \{1, \ldots, b_{C.R} \mid R \in \omega_T(\alpha) \text{ and } D \in \Psi_T(\alpha i) \} \leq n $$

as required.

2. $(\leq n R D)$ is marked in $\Psi_T(\alpha)$. Then there exists a $\beta \in \{1, \ldots, b_{C.R}\}^*$ such that $\lnv(R) \in \omega_T(\alpha i)$ and $D \in \Psi_T(\beta)$. First assume $\pi(\beta) \in K$. This implies that we have

$$ \{ y \in S \mid (\pi(\alpha), y) \in R^T \text{ and } y \in D^T \} = K \setminus \{ \pi(\beta) \} $$

during the induction step generating successors for $\alpha$. Together with $\sharp K \leq n$, we obtain

$$ \sharp \{ i \in \{1, \ldots, b_{C.R} \mid R \in \omega_T(\alpha i) \text{ and } D \in \Psi_T(\alpha i) \} \leq n $$

as required. Now assume $\pi(\beta) \notin K$. Since $\lnv(R) \in \omega_T(\alpha i)$ and $D \in \Psi_T(\beta)$, we have $(\pi(\alpha), \pi(\beta)) \in R^T$ and $\pi(\beta) \in D^T$ by (a) and (b). Since $\pi(\alpha) \in (\leq n R D)^T$ and $\pi(\beta) \notin K$, $\mathcal{Q}$-$\mathcal{SHIQ}$ semantics implies that $\sharp K < n$. Moreover, $\pi(\beta) \notin K$ implies

$$ \{ y \in S \mid (\pi(\alpha), y) \in R^T \text{ and } y \in D^T \} = K $$

during the induction step generating successors for $\alpha$. Together with $\sharp K < n$, this yields

$$ \sharp \{ i \in \{1, \ldots, b_{C.R} \mid R \in \omega_T(\alpha i) \text{ and } D \in \Psi_T(\alpha i) \} < n $$

as required.
(M9) Immediate from the construction of $T$.

(M10) Let $\ell = (\Psi_0, \omega_0, V_0, E_0, \tau_0)$ and let $\ell  = (\Psi_i, \omega_i, V_i, E_i, \tau_i)$ for $1 \leq i \leq b_{C, R}$.

We first establish the following claim:

Claim: if $\exists Rg_1, g_2. P$ appears unmarked in $\Psi_0$, then there exists an $i \in \{1, \ldots, b_{C, R}\}$ such that $g_1 \in V_i, g_2 \in V_0, R \in \omega_i$ and $g_1 (\pi(\ell)) P g_2 (\pi(\ell))$.

Proof: Assume that $\exists Rg_1, g_2. P$ appears unmarked in $\Psi_0$. By (a), we have $\pi(\ell) \in (\exists Rg_1, g_2. P)^T$. Thus, by Property 4 of $W(\cdot)$, there exists a $y \in W(\pi(\ell))$ such that $(\pi(\ell), y) \in R^T$ and $g_1 (y) P g_2 (\pi(\ell))$ (implying that $g_1 (y)$ and $g_2 (\pi(\ell))$ are defined). By definition of $T$, $\exists Rg_1, g_2. P$ appearing unmarked in $\Psi_0$, implies that either (i) $\pi(\ell) = x_{root}$ or (ii) there exists a $\beta$ such that $\alpha = \beta\ell$ and we have either $\text{Inv}(R) \notin \omega_0$ or $g_1 (y) P g_2 (\pi(\ell))$ does not hold. In Case (i), we clearly have $y \in S = W(\pi(\ell))$ during the induction step generating successors for $\alpha$. In Case (ii), (b) implies that $(\pi(\ell), \pi(\beta)) \notin R^T$ or $g_1 (\pi(\beta)) P g_2 (\pi(\ell))$ does not hold. This implies $y \neq \pi(\beta)$ and thus we have $y \in S$ during the induction step generating successors for $\alpha$ in both Case (i) and (ii). Hence, there exists an $i \in \{1, \ldots, b_{C, R}\}$ such that $\pi(\ell) = y, R \in \omega_i$, and $g_1 (\pi(\ell)) P g_2 (\pi(\ell))$. Moreover, since $g_1 (y)$ and $g_2 (\pi(\ell))$ are defined, the construction of $T$ and definition of $\mathcal{I}(\cdot, \cdot)$ implies that $g_1 \in V_i$ and $g_2 \in V_0$.

For each $\exists Rg_1, g_2. P$ appearing unmarked in $\Psi_0$, the $i \in \{1, \ldots, b_{C, R}\}$ provided by the claim is denoted by $\lambda(\exists Rg_1, g_2. P)$.

We define a constraint graph $G = (V, E, \tau)$ as follows:

\[
V := V_0 \cup \{ig \mid 1 \leq i \leq b_{C, R} \text{ and } g \in V_0\}
\]

\[
E := F \cup E_0 \cup \{(ig_1, ig_2, P) \mid 1 \leq i \leq b_{C, R} \text{ and } (g_1, g_2, P) \in E_i\}
\]

\[
\tau := \tau_0 \cup \{(ig, P_\alpha) \mid 1 \leq i \leq b_{C, R} \text{ and } (g, P_\alpha) \in \tau_i\}
\]

where $F$ is defined in the following way:

\[
F := \{(ig_1, g_2, P) \mid \exists Rg_1, g_2. P \text{ appears unmarked in } \Psi_0 \text{ and } \lambda(\exists Rg_1, g_2. P) = i\}
\]

\[
\cup \{(g_1, ig_2, P) \mid \exists Rg_1, g_2. P \text{ appears marked in } \Psi_i\}
\]

\[
\cup \{(ig_1, g_2, P) \mid \forall Rg_1, g_2. P \in \Psi_0, R \in \omega_i, g_1 \in V_i, \text{ and } g_2 \in V_0\}
\]

\[
\cup \{(g_1, ig_2, P) \mid \forall Rg_1, g_2. P \in \Psi_i, \text{Inv}(R) \in \omega_i, g_1 \in V_0, \text{ and } g_2 \in V_i\}
\]

It is not hard to verify that $G$ is well-defined, i.e., that (i) if $\exists Rg_1, g_2. P$ appears unmarked in $\Psi_0$ and $\lambda(\exists Rg_1, g_2. P) = i$, then $ig_1, g_2 \in V$, and (ii) if $\exists Rg_1, g_2. P$ appears marked in $\Psi_i$, then $g_1, ig_2 \in V_i$: for (i), we just need to use the above claim, and for (ii), it suffices to refer to the way in which concepts inside node labels are marked during the construction of $T$. Moreover, it is readily checked that $G$ is a tuple-graph for $(T(\alpha), T(\alpha_1), \ldots, T(\alpha_{b_{C, R}}); V, E, \tau)$ are clearly of the form described in Definition 4.3 and it is not hard to verify that (G1) to (G4) are satisfied (use the above Claim for (G1) and the way in which concepts inside node labels are marked for (G2)). To show that (M10) is satisfied, it thus
remains to show that \( G \) has a consistent normalization. However, since it is easily seen that every solution for a constraint graph induces a consistent normalization of this constraint graph, it suffices to show that \( G \) itself is consistent.

Define a mapping \( \tau \) from \( V \) to \( \mathbb{Q} \) as follows:

\[
(\tau) := g^T(\pi(\alpha)) \quad \text{and} \quad (i\tau) := g^T(\pi(\alpha_i)).
\]

We show that \( \tau \) is a solution for \( G \):

- Let \((v, P_q) \in \tau\). Then either (i) \( v = g \) for some \( g \in \mathbb{N}_\mathbb{F} \) or (ii) \( v = i\tau \) for some \( i \in \{1, \ldots, b_{C,R} \} \) and \( g \in \mathbb{N}_\mathbb{F} \). In Case (i), we have \((g, P_q) \in \tau_0\) by definition of \( G \). By construction of \( T \) and definition of \( \mathcal{I}(\cdot, \cdot) \), this implies \( g^T(\pi(\alpha)) P_q \). By definition of \( \cdot \), we thus have \((g) P_q \). Similarly, in Case (ii) we have \((g, P_q) \in \tau_1 \) which implies \( g^T(\pi(\alpha_i)) P_q \) and thus \((i\tau) P_q \).

- Let \((v_1, v_2, P) \in E\). By definition of \( G \), we can distinguish the following cases:

1. \( v_1 = g_1 \) and \( v_2 = g_2 \) for some \( g_1, g_2 \in \mathbb{N}_\mathbb{F} \). By definition of \( G \), we have \((g_1, g_2, P) \in V_0\). By construction of \( T \) and definition of \( \mathcal{I}(\cdot, \cdot) \), this implies \( g_1^T(\pi(\alpha)) P g_2^T(\pi(\alpha)) \). Hence, \((g_1) P (g_2)\).

2. \( v_1 = i\tau g_1 \) and \( v_2 = i\tau g_2 \) for some \( i \in \{1, \ldots, b_{C,R} \} \) and \( g_1, g_2 \in \mathbb{N}_\mathbb{F} \). Then we have \((g_1, g_2, P) \in V_1\) and can continue as in the previous case.

3. \( v_1 = i\tau g_1 \) and \( v_2 = g_2 \) for some \( i \in \{1, \ldots, b_{C,R} \} \) and \( g_1, g_2 \in \mathbb{N}_\mathbb{F} \). By construction of \( F \), we can distinguish two subcases:
   - there exists some concept \( \exists_R g_1, g_2, P \) such that \( \exists_R g_1, g_2, P \) appears unmarked in \( \Psi_0 \) and \( \lambda(\exists_R g_1, g_2, P) = i \). By the above Claim, we have \( g_1^T(\pi(\alpha)) P g_2^T(\pi(\alpha)) \) which clearly implies \((i\tau) P (g_2)\).
   - \( \forall_R g_1, g_2, P \in \Psi_0, R \in \omega_i, g_1 \in V_i, \text{ and } g_2 \in V_0 \). By (a), \( \forall_R g_1, g_2, P \in \Psi_0 \) implies \( \pi(\alpha) \in \langle \forall_R g_1, g_2, P \rangle \). By construction of \( T \) and definition of \( \mathcal{I}(\cdot, \cdot) \), \( R \in \omega_i \) implies \( (\pi(\alpha), \pi(\alpha)) \in \mathcal{R} \). \( g_1 \in V_i \) implies that \( g_1^T(\pi(\alpha)) \) is defined, and \( g_2 \in V_0 \) implies that \( g_2^T(\pi(\alpha)) \) is defined. Thus \( g_1^T(\pi(\alpha)) P g_2^T(\pi(\alpha)) \) by \( \mathbb{Q}-\mathbb{S}\mathbb{H}\mathbb{I}\mathbb{Q} \) semantics and \((i\tau) P (g_2)\) by definition of \( \cdot \).

4. \( v_1 = g_1 \) and \( v_2 = i\tau g_2 \) for some \( i \in \{1, \ldots, b_{C,R} \} \) and \( g_1, g_2 \in \mathbb{N}_\mathbb{F} \). By construction of \( F \), we can distinguish two subcases:
   - there exists some concept \( \exists_R g_1, g_2, P \) that appears marked in \( \Psi_1 \).
     By construction of \( T \) (in particular the marking of concepts in node labels), we have \( \text{lnv}(R) \in \omega_i \) and \( g_1^T(\pi(\alpha)) P g_2^T(\pi(\alpha)) \). It remains to refer to the definition of \( \cdot \).
   - \( \forall_R g_1, g_2, P \in \Psi_i, \text{ lnv}(R) \in \omega_i, g_1 \in V_i \), \( g_2 \in V_1 \). By (a), \( \forall_R g_1, g_2, P \in \Psi_i \) implies \( \pi(\alpha) \in \langle \forall_R g_1, g_2, P \rangle \). By construction of \( T \) and definition of \( \mathcal{I}(\cdot, \cdot) \), \( \text{lnv}(R) \in \omega_i \) implies \( (\pi(\alpha), \pi(\alpha)) \in \mathcal{R} \). \( g_1 \in V_i \) implies that \( g_1^T(\pi(\alpha)) \) is defined, and \( g_2 \in V_i \) implies that \( g_2^T(\pi(\alpha)) \) is defined. Thus \( g_1^T(\pi(\alpha)) P g_2^T(\pi(\alpha)) \) by \( \mathbb{Q}-\mathbb{S}\mathbb{H}\mathbb{I}\mathbb{Q} \) semantics and \((g_1) P (i\tau g_2)\) by definition of \( \cdot \).

\( \square \)
6 Defining Looping Automata

To prove decidability of $Q$-$SHIQ$-concept satisfiability, it remains to define a looping automaton $A_{C, \mathcal{R}}$ for each concept $C$ and role hierarchy $\mathcal{R}$ such that $A_{C, \mathcal{R}}$ accepts exactly the Hintikka-trees for $C$ and $\mathcal{R}$. Using the notion of Hintikka-tuples from Definition 4.3, this is rather straightforward.

**Definition 6.1.** Let $C$ be a concept in PNF, $\mathcal{R}$ be a role hierarchy, and $b_{C, \mathcal{R}}$ be as in Definition 4.3. The looping automaton $A_{C, \mathcal{R}} = (Q, M, \Delta, I)$ is defined as follows:

- $Q := M := \Gamma_{C, \mathcal{R}}$
- $I := \{ (\Psi, \omega, V, E, \tau) \in Q \mid C \in \Psi \text{ and all concepts in } \Psi \text{ are unmarked} \}$.
- $\Delta \subseteq Q^{b_{C, \mathcal{R}}+2}$ such that $(L, L', L_1, \ldots, L_{b_{C, \mathcal{R}}}) \in \Delta$ iff
  \begin{align*}
  &L = L' \text{ and} \\
  &(L, L_1, \ldots, L_{b_{C, \mathcal{R}}}) \text{ is a Hintikka-tuple.}
  \end{align*}

\[ \diamond \]

As a consequence of the following lemma and Lemmas 5.3 and 5.4, we can reduce satisfiability of concepts (in PNF) w.r.t. role hierarchies to the emptiness of the language accepted by looping automata.

**Lemma 6.2.** $T$ is a Hintikka-tree for $C$ and $\mathcal{R}$ iff $T \in L(A_{C, \mathcal{R}})$.

**Proof.** Let $C$ be a concept, $\mathcal{R}$ a role hierarchy, and $b_{C, \mathcal{R}}$ as in Definition 4.3.

For the “if” direction, let $r$ be a run of $A_{C, \mathcal{R}}$ on $T$. By definition of runs and of $\Delta$, we have

$$r(\alpha) = T(\alpha) \text{ for all } \alpha \in \{1, \ldots, b_{C, \mathcal{R}}\}^*.$$ 

Hence, it remains to be shown that $r$ is a Hintikka-tree for $C$ and $\mathcal{R}$, which is straightforward: (i) by definition of $Q$, $r$ is a $\Gamma_{C, \mathcal{R}}$-tree; (ii) since, by definition of runs, $r(\epsilon) \in I$, (T1) and (T2) are satisfied; and (iii) by definition of runs and of $\Delta$, (T3) is satisfied.

Now for the “only if” direction. It is straightforward to check that $T$ itself is a run of $A_{C, \mathcal{R}}$ on $T$: (i) by definition of Hintikka-trees and $A_{C, \mathcal{R}}$, $T(\alpha) \in Q$ for all $\alpha \in \{1, \ldots, b_{C, \mathcal{R}}\}^*$; (ii) by (T1), (T2), and definition of $I$, we have $T(\epsilon) \in I$; (iii) by (T3) and by definition of $\Delta$, we have $(T(\alpha), T(\alpha), T(\alpha_1), \ldots, T(\alpha_k)) \in \Delta$ for all $\alpha \in \{1, \ldots, b_{C, \mathcal{R}}\}^*$. \[ \square \]

It is an immediate consequence of Lemmas 3.3, 5.3, 5.4, and 6.2 and the decidability of the emptiness problem of looping automata [21] that satisfiability of $Q$-$SHIQ$-concepts w.r.t. role hierarchies is decidable. However, the presented automata-based algorithm additionally provides us with a tight complexity bound if the numbers inside number restrictions are assumed to be encoded unarily. We use $|C|$ to denote the length of the concept $C$ and $|\mathcal{R}|$ to denote the number of role inclusions in the role hierarchy $\mathcal{R}$. 

35
Theorem 6.3. If numbers inside number restrictions are encoded unarily, then satisfiability of $\mathbb{Q}$-$\mathcal{SHIQ}$-concepts w.r.t. role hierarchies is $\text{ExpTIME}$-complete.

Proof. The lower bound is an immediate consequence of the fact that $\mathcal{SHIQ}$-concept satisfiability is $\text{ExpTIME}$-hard [20]. For the upper bound, we need to show that the size of $\mathcal{A}_{C,R}$ is exponential in $|C| + |R|$, which clearly implies that $\mathcal{A}_{C,R}$ can be computed in exponential time. Indeed, if this is established, we can use Lemmas 3.3, 5.3, 5.4, and 6.2 together with the fact that the emptiness problem for looping automata $\mathcal{A}_{C,R}$ is in $\text{PSPACE}$ [21] to conclude that satisfiability of $\mathbb{Q}$-$\mathcal{SHIQ}$-concepts w.r.t. role hierarchies can be decided in deterministic exponential time. Hence, let us investigate the size of $\mathcal{A}_{C,R} = (Q, M, \Delta, I)$. It is straightforward to verify that the cardinality of $\mathcal{cl}(C, R)$ is quadratic in $|C| + |R|$. Hence, using the definition of $\mathcal{A}_{C,R}$, Hintikka-labels, and Hintikka-sets, it is not hard to check that the cardinality of $Q$ and $M$ are exponential in $|C| + |R|$. Again by definition of $\mathcal{A}_{C,R}$, this implies that the cardinalities of $I$ and $\Delta$ are also exponential in $|C| + |R|$. Hence, the size of $\mathcal{A}_{C,R}$ is exponential in $|C| + |R|$. \qed

Since subsumption can be reduced to (un)satisfiability, $\mathbb{Q}$-$\mathcal{SHIQ}$-concept subsumption w.r.t. role hierarchies is also $\text{ExpTIME}$-complete.

7 Future Work

In this paper, we have presented the Description Logic $\mathbb{Q}$-$\mathcal{SHIQ}$, which extends the well-known DL $\mathcal{SHIQ}$ with several concrete domain concept constructors that allow to represent numerical knowledge, such as knowledge about the age, weight, or height of real-world entities. As argued in the introduction, $\mathbb{Q}$-$\mathcal{SHIQ}$ is a contribution to several interesting application areas. However, we regard the results presented in this paper only as a first step: first, it is currently unknown whether some of the restricting assumptions made in the definition of $\mathbb{Q}$-$\mathcal{SHIQ}$ are really necessary to ensure decidability of reasoning; second, to make $\mathbb{Q}$-$\mathcal{SHIQ}$ usable for applications, there still remains work to be done such as finding a tableau-style algorithm or devising an algorithm for finite model reasoning. More precisely, we would like to complete the research on $\mathbb{Q}$-$\mathcal{SHIQ}$ by the following investigations:

1. To make $\mathbb{Q}$-$\mathcal{SHIQ}$ available for use in applications, modern DL systems like Fact and RACER, which are implementations of the $\mathcal{SHIQ}$ Description Logic, need to be extended to $\mathbb{Q}$-$\mathcal{SHIQ}$. Unfortunately, the results presented in this paper cannot immediately be used to do this: the above mentioned DL systems are based on tableau-style algorithms while the decision procedure described in this paper is automata-based. Hence, it would be interesting to devise a tableau-based algorithm for $\mathbb{Q}$-$\mathcal{SHIQ}$-concept satisfiability. As discussed in [13] in the context of $\mathcal{TDL}$, the automata-based algorithm presented in this paper can provide important information (i.e., a "regular model property") for this task.

2. If $\mathbb{Q}$-$\mathcal{SHIQ}$ is to be used for reasoning about ER diagrams as sketched in the introduction, one is usually not interested in the satisfiability of concepts in arbitrary models, but rather in the satisfiability in finite models [3]. These two problems do not
coincide since $\mathcal{SHIQ}$, and hence also $Q-\mathcal{SHIQ}$, lacks the finite model property [10]. Thus, it is worthwhile to investigate the decidability and complexity of finite model reasoning with $Q-\mathcal{SHIQ}$.

(3) For some applications, it is desirable to refer to natural numbers instead of rational numbers. As a simple example, consider the concept

$$\exists (\text{left-neighbor numchild}.) = 2 \land \exists (\text{left-neighbor numchild}.), (\text{numchild}). <$$

$$\land \exists (\text{right-neighbor numchild}) = 3 \land \exists (\text{numchild}), (\text{right-neighbor numchild}). <,$$

where numchild is a concrete feature representing the number of children. Clearly, the above concept should be unsatisfiable. In $Q-\mathcal{SHIQ}$, however, this concept is satisfiable since, in a model, the number of children of the described person may be $2.5$. It would thus be interesting to add a concept constructor $\exists g.\text{nat}$ to $Q-\mathcal{SHIQ}$ expressing that the filler of the concrete feature $g$ is a natural number. If the extended logic is decidable, then at least it seems to require some serious modifications of the presented decision procedure: as noted in [15] in the context of $\mathcal{TDL}$, Theorem 3.7 does not hold if the satisfiability of constraint graphs over non-dense structures such as $\mathbb{N}$ is considered. However, if $Q-\mathcal{SHIQ}$ is extended with an $\exists g.\text{nat}$ constructor, then concepts of the resulting logic can clearly be used to describe constraint graphs all of whose nodes are labeled with the $\text{nat}$ predicates. This means that, effectively, we have to decide satisfiability of these constraint graphs over $\mathbb{N}$.

(2) In the current version of $Q-\mathcal{SHIQ}$, the syntactic form of paths $U_1$ and $U_2$ inside the constructors $\exists U_1, U_2. P$ and $\forall U_1, U_2. P$ is restricted. Can we allow arbitrary paths here without losing decidability? Our feeling is that we can, and that the resulting logic is still in $\text{ExpTime}$, but a proof is yet to be found.

(3) In this paper, we have disallowed the use of transitive roles inside the constructors $\exists R g_1, g_2. P$ and $\forall R g_1, g_2. P$. What happens w.r.t. decidability and complexity if transitive roles are admitted?

(4) The $\text{ExpTime}$ upper bound established in this paper requires numbers inside number restrictions to be coded unarily. Does the upper bound still apply if binary coding of numbers is assumed? Note that, in [20], Tobies describes an automata-based decision procedure to show $\text{ExpTime}$-completeness of reasoning with the Description Logic $\mathcal{ALCQIb}$ with binary coding of numbers. Since $\mathcal{ALCQIb}$ is rather closely related to $\mathcal{SHIQ}$, one could think that a straightforward combination of Tobies' techniques with the ones presented in the current paper yields an $\text{ExpTime}$ upper bound for $Q-\mathcal{SHIQ}$ with binary coding of numbers. However, it seems that there are some intricate interactions between Tobies' approach to handle number restrictions and our way to deal with the "numerical part" of $Q-\mathcal{SHIQ}$.

It is interesting to note that the expressive power provided by $Q-\mathcal{SHIQ}$ is in many aspects already on the "border" to undecidability. This concerns the $\mathcal{SHIQ}$-part of the logic (recall that admitting non-simple roles inside number restrictions destroys decidability) as well as the numerical part. For example, it seems rather unlikely that any kind of arithmetics can be added to $Q-\mathcal{SHIQ}$ without losing decidability. More precisely, it follows from results in [16; 14] that the addition of a concept constructor expressing the addition of two numbers already yields undecidability of reasoning.
